This volume is the second part of three part series on Dermaptera under the Fauna of India series covering India, Pakistan, Nepal, Bhutan, Bangladesh and Sri Lanka. It deals with Anisolaboidea which included two families, 9 subfamilies, 20 genera and 83 species. Some important modifications in the classification of the order are proposed. The description of the species are based upon fresh specimens collected by the author and already present in the Zoological Survey of India and other world Museums and Institutes. It is hoped this volume will be of great help to research workers and others interested in the group.

FOREWORD

Much of the information on Dermaptera from India and adjacent countries is through scattered papers. It is one of the aims of the Zoological Survey of India to bring out consolidated publications on various groups of animals of which the Fauna of India series is the foremost.

The present volume is second in the series of Fauna of India Dermaptera, Part I by Dr. G. K. Srivastava. Treatment of the subject is exhaustive but on the same lines of previous part. In this volume altogether 83 species belonging to 20 genera under nine subfamilies and two families viz. Anisolabididae and Labiduridae of superfamily Anisolaboidea are dealt with. Observations recorded for various species are based on a large number of specimens in the Zoological Survey of India and other world Museums and Institutes.

Dr. Srivastava is engaged in the study of Dermaptera for a little over three decades and is an authority on the subject. It is hoped that this volume would be of a great help to workers and others interested in this group of insects.

J.R.B. Alfred
Director
Zoological Survey of India
This is the second part of the three part series on Dermaptera under the *Fauna of India* series. The species occurring in India, including Andaman and Nicobar and Lakshadeep group of Islands, Pakistan, Nepal, Bhutan, Bangladesh and Sri Lanka belonging two families, namely Anisolabididae and Labiduridae under the superfamily Anisolaboidea are dealt with. The concluding Part III would deal with superfamily Forficuloidae.

Some important modifications in the classification of the order at supergeneric level are proposed. Two suborders Catadermaptera and Eudermaptera proposed by Steinmann are treated as two sections under suborder Forficulina of free living Dermaptera. Important additions to subfamilies are Irdexinae, Homotaginae, Rudraxinae and Placolabidinae. A fresh key to supergeneric taxa from the area is prepared incorporating above subfamilies.

Treatment of the main text is on the pattern of Part I under this series. Altogether, 83 species belonging to 20 genera, 9 subfamilies and two families of Superfamily Anisolabiodea are treated. The description of each species provides synonymies followed by the diagnostic features giving information on distribution, types and general remarks. Under distribution the localities of such identified specimens which have not been reported earlier are mentioned with their repositories.

Species is a living entity in nature and its dynamism is exhibited through intraspecific variations within the individuals of same and different populations. This aspect is discussed, in detail, whereever possible.

Various locality records for species mentioned in literature were checked through specimens, if available from the area under study. However, in certain cases records from other areas were confirmed through photographs given by Sakai in his publication under the title *Dermapterorum catalogus*.

Observations for various species are based upon fresh and already preserved specimens in the Zoological Survey of India and other institutes in the country and abroad.

INTRODUCTION

The present work forms the second part of the *Fauna of India, Dermaptera Pt. I Superfamily Pygidicranioidea* published in the year 1988 by the author. It deals with two families, Anisolabididae and Labiduridae, under superfamily Anisolaboidea. The third and the last part would include superfamilies Apachyoidea and Forficuloidea.

For the sake of completion, under the headings ‘Abbreviations used’ and ‘References’ besides additional ones all those already mentioned in Pt. I are given.

Altogether 83 species belonging to 20 genera, 9 subfamilies are treated in this part. It includes, the description of a new species, *Gonolabis krishnappai* besides synonymising, *Labidurodes orientalis* Ramamurthi, 1968 under *Titanolabis maindroni* (Borelli, 1911); *Epilandex bazyluki* Steinmann, 1979 under *Epilandex burri* (Borelli, 1921); *Metisolabis fulgens* Steinmann, 1989 under *Metisolabis caudelli* (Bolivar, 1897) and *Labidura cryptera* Liu, 1946, *L. elegans* Liu, 1946 and *L. orientalis* Liu, 1946 under *Labidura riparia* (Pallas, 1773). The description of various taxa is on the same lines as in the previous part.

Steinmann (1989a) proposed two Suborders and three Sections to accommodate seven families which were earlier included under Suborder Forficulina. Some modifications in supergeneric classification have been proposed, details of which are provided in the following pages.

The synonymies given under each species were verified with the specimens recorded from India and adjacent countries. However, for records from other areas, which could not be checked with actual specimens, the work of Sakai (1987) providing photographs of such specimens, preserved in various world museums was of a great help.

**CLASSIFICATION**

The supergeneric classification followed in the present work is after Steinmann (1975) with certain modification by Srivastava (1988).

Steinmann, (1989a) divided the Order Dermaptera into two Suborders, *viz.* Catadermaptera and Eudermaptera which are treated here as two Sections. And three sections, namely Protodermaptera, Mesodermaptera and Paradermaptera included under Catadermaptera by him are not considered valid.

The superfamily, family and subfamily names used are Anisolaboidea, Anisolabididae and Anisolabidinae in place of Carcinophoroidea, Carcinophoridae and Carcinophorinae for the sake of priority.

Important additions to subfamilies are Irdexinae, Homotaginae and Rudraxina erected by Srivastava (1985, 1995). Besides, Placolabidinae has been proposed by Srivastava (1999) for the reception of *Placolabis* Bey-Bienko.

Following is outline of classification of free living Dermaptera included under Suborder FORFICULINA.

KEY TO THE SUPER-GENERIC TAXA REPRESENTED
FROM INDIAN SUBCONTINENT
(modified after Steinmann, 1975 and Srivastava, 1988)

1(30). Male genitalia with basal portion (proparameres) divisible into two halves
(may be separated apically or united throughout) with two functional distal
lobes, sometimes one of them reduced ......................... CATADERMAPTERA

2(9). Neck blattoid type i.e., anterior and posterior cervical sclerites anterior to
prosternum separated from each other but hind margin of posterior sclerite
may be separate or fused with apical margin of prosternum.....................
.............................................................................. PYDIGINCRANOIDEA (PYGIDICRANIDAE)

3(4). Antennal segments 4-5 transverse, 25 segmented or more......................
........................................................................................................... PYGIDICRANINAE Verhoeff

4(3). Antennal segments 4-6 longer than broad, 20 segmented or less

5(6). Femora compressed with sharp longitudinal ridges; male genitalia with
parameres armed internally in various ways ........ DIPLATYINAE Verhoeff
6(5). Femora not compressed, usually smooth, occasionally with a faint ridge; male genitalia with parameres simple (unarmed)

7(8). Body convex, covered with thick characteristic setae and long pubescence; femora occasionally with a faint ridge; pygidium with hind margin projecting; forceps cylindrical.................................................. ECHINOSOMATINAE Burr

8(7). Body depressed, glabrous and smooth; femora devoid of any ridge; pygidium vertical with hind margin not projecting; forceps trigonal in basal one third, afterwards depressed ............................................. PROLABISCINAE Bey-Bienko

9(2). Neck forficuloid type, i.e., anterior and posterior cervical sclerites fused and the hind margin of latter joined with anterior margin of prosternum

10(29). Pygidium in both sexes vertical with its hind margin not free; forceps partially trigonal near base and moderately depressed afterwards or cylindrical ...... .................................................................................................. ANISOLABOIDEA

11(24) Male genitalia, if virga present, usually not wider at base and without a sinuous inner tube; otherwise denticulate pads present ................................................. ANISOLABIDIDAE Verhoeff

12(13). Body strongly depressed; male forceps strongly curved. female ones elongated .................................................................................................. PLATYLABIINAE Burr

13(12). Body not strongly depressed; weakly or strongly convex; forceps various

14(15). Meso-and Metasternum oblong and both with posterior margin convex or tongue shaped................................................................. TITANOLABIDINAE Srivastava

15(14). Meso-and Metasternum quadrate, former briefly convex or truncate posteriorly and latter narrowed posteriorly with hind margin truncate

16(17). Mesosternum briefly convex posteriorly ............ ANISOLABIDINAE Verhoeff

17(16). Mesosternum truncate posteriorly

18(21). 1st antennal segment equal or longer than the distance between antennal bases

19(20). Mesonotum laterally with a well defined ridge or convexity along its whole length, often obsolete in posterior half .......... BRACHYLABIDINAE Burr

20(19). Mesonotum without any ridge laterally .... ANTISOLABIDINAE Steinmann

21(18). 1st antennal segment shorter than the distance between antennal bases

22(23). Male genitalia with one distal lobe atrophied and virga much reduced ...... ................................................................................................. ISOLABOIDINAE Brindle

23(22). Male genitalia with both distal lobes and virga well developed ................. ................................................................. PARISOLABIDINAE Verhoeff
24(11). Male genitalia with distinct virga, dilated at base with a distinct inner sinus tube.................................................................................................. LABIDURIDAE Verhoeff

25(26). Mesosternum strongly narrowed posteriorly with tip extending up to middle of metasternum .......................................................... ALLOSTETHINAE Burr

26(25). Mesosternum posteriorly wider, not strongly narrowed posteriorly

27(28). Elytra with a sharp ridge along the costal margin; legs relatively short, posterior femora not longer than pronotum............... NALINAE Steinmann

28(27). Elytra without any sharp ridge along the costal margin; legs longer, posterior femora longer than pronotum........................................... LABIDURINAE Burr

29(10). Pygidium in both sexes forming a flat process with hind margin free; forceps with branches broad and flat .............................................................. APACHYOIDEA (APACHYIDAE) (APACHYINAE)

30(1). Male genitalia with a median basal portion (proparamere) and single distal lobe ................................................................. EUDERMAPTERA (FORFICULOIDEA)

31(40). Second tarsal segment simple ......................... SPONGIPHORIDAE Burr

32(35). Second tarsal segment longer than broad

33(34). Hind second tarsal segment, in profile, almost of uniform width, only scarcely narrowed basally and slightly shorter than third, first segment slightly longer than the combined length of last two segments ......................................................... HOMOTAGINAE Srivastava

34(33). Hind second tarsal segment, in profile, narrow basally, about half and long as the third, first segment slightly shorter than the combined length of second and third .................................................................. SPONGIPHORINAE Burr

35(32). Second tarsal segment broader than long or about as broad as long

36(37). Hind tarsi comparatively long & slender, 1st segment over five times longer than broad; elytra smooth, occasionally costal margin with a row of small tubercles, each with a thick setae....................... IRDEXINAE Srivastava

37(36). Hind tarsi comparatively short and thick, 1st segment three to four times longer than broad

38(39). Body strongly depressed or flattened, head flat; pronotum anteriorly narrowed forming a sort of neck ........................................ SPARATTINAE Burr

39(38). Body weakly depressed or convex; head convex; pronotum gently narrowed but not forming a sort of neck ........................................ LABIINAE Burr

40(31). Second tarsal segment dilated or produced in the form of a narrow lobe below the third segment
41(44). Antennae 17-22 segmented; second tarsal segment spiniform, extending below third up to the middle, visible from sides only...... CHELISOCHIDAE Burr

42(43). Elytra along the costal margin with a sharp ridge, often not complete...... ................................................................. CHELISOCHELLINAE Steinmann

43(42). Elytra along the costal margin without any ridge .................................................. CHELISOCHINAE Burr

44(41). Antennae 12-16 segmented; second tarsal segment lobed, visible from above on either side of third segment ............... FORFICULIDAE Stephens

45(48). Antennal joints long and slender, 4th longer than the 3rd or almost equal, both of similar build, i.e., slender

46(47). Elytra with a sharp ridge along the costal margin.............................................. COSMIELLINAE Steinmann

47(46). Elytra without any ridge along the costal margin .................................................. OPISTHOCOSMIINAE Verhoeff

48(45). Antennal joints shorter and wider, occasionally apical ones long and slender, 4th shorter or almost equal to 3rd but former always stouter

49(52). Mesosternum broader than long

50(51). Elytra with a sharp ridge along the costal margin.............................................. ALLODAHLIINAE Verhoeff

51(50). Elytra without any ridge along the costal margin .... ANECHURINAE Burr

52(49). Mesosternum about as broad as long

53(54). Forceps generally curved or elongated, cylindrical, not deplanae at base.... ................................................................. EUDOHRNIINAE Burr

54(53). Forceps in most of the species deplanate in basal half or less, afterwards cylindrical or depressed........................ FORFICULINAE Burr

SYSTEMATIC ACCOUNT

Superfamily ANISOLABOIDEA

Anisolaboidea Sakai, 1982, *Bull. Daito Bunka Univ.*, 20 : 22 (name for Carcinophoridae);

This superfamily is characterised by the shape of pygidium, in both the sexes, vertical with hind margin fused and forceps, trigonal in basal part, afterwards depressed.
Family ANISOLABIDIDAE

Size large to very small; body strongly flattened or normal i.e. weakly depressed. Winged or apterous; often elytra abbreviated and wing wanting. Neck forficuloid type, i.e. anterior and posterior cervical sclerites fused and the hind margin of latter joined with anterior margin of prosternum. Forceps short and simple and in males slightly or strongly curved. Male genitalia with paired penis lobes, from each arises distal lobes, sometimes one of them reduced and flexed forward.

Distribution : World wide.

Subfamily PLATYLABIINAE

This subfamily is characterised by strongly depressed body; forceps sickle shaped and genitalia with paired penses, both distal lobes well developed, one of them flexed forward, and virga distinct.

Type genus : Platylabia Dohrn, 1867.

Distribution : Oriental Region, especially in South East Asia.

Genus Platylabia Dohrn

Palex Burr, 1910, *Fauna British India, Dermaptera* : 68 (Type-species: *Palex sparattoides* Bormans, 1900 = *Platylabia major* Dohrn, 1867).

Body strongly flattened. Head transverse, smooth. Antennae 24–segmented, 1st stout, subclavate, shorter than the distance between antennal bases; 2nd about as long as broad; 3rd long and slender; 4th globular or subcalvate; 5th longer than 4th, subclavate; 6th longer than 5th; shorter or as long as 3rd, remaining gradually increasing in length and thinning. Elytra and wings well developed, latter often abbreviated. Legs normal, hind metatarsus shorter than protarsus, latter almost equal to combined length of meso-and metatarsus. Prosternum about three times longer than broad, not constricted between fore coxae; meso-sternum quadrate hind margin straight and metasternum transverse faintly emarginate in middle posteriorly. Pygidium vertical. Male genitalia with parameres narrow or flattened, distal lobes, paired one of which directed forward; virga present.

*Type-species*: *Platylabia major* Dohrn, 1867 (Designated by Kirby, 1891, *J. Linn. Soc. (Zool.)* 23 : 518).

*Remarks*: The genus *Platylabia* was described by Dohrn (1867) with four new species of which first one, *P. major*, is now considered as the type of the genus and all others belong to other genera. The original description of *P. major* is based on a female from Celebes. Subsequently this species was found to occur throughout the Oriental Region. Zacher (1910, fig. 11) for the first time figured the male genitalia of this species which possesses parameres about three times longer than broad, slightly broadened and turned externally near apex and provided with a faint tubercle close to inner apical angle. Distal lobes are provided with a distinct fine tubular virga. Therefore, those specimens which possess similar genitalia and agree with the original description and other subsequent diagnostic characters provided by Dubrony A. de (1879) and Burr (1910) are referred to this species. Two other species have been described by Srivastava (1981) which differ from the type species by the shape of male parameres besides other peculiarities. Unfortunately females of all the three species look almost alike and cannot be satisfactorily placed to a particular species in the absence of males.

Only two species, *P. nathani* Srivastava and *P. brindlei* Srivastava are known from India and *P. major* (Dohrn), although widely recorded from the Oriental Region, has not been so far reported from India.

*Distribution*: Oriental Region.

**Key to the species (based on males only)**

1(2). Pronotum with sides straight; parameres narrower, apices obtuse; distal lobes with virga short and curved ................................................. *P. nathani* Srivastava
2(1). Pronotum with sides feebly convex in middle; parameres comparatively broader, anteriorly with a small tubercle near inner apical angle; distal lobes with virga tubular (not curved) ............................................ P. brindlei Srivastava

**Platylabia nathani** Srivastava

(Figs. 1-3)

*Platylabia nathani* Srivastava, 1981, *Bull. zool. Surv. India*, 4 (1) : 106, figs. 6-10 (Male, Female; India : Tamil Nadu, Cinchona, 3500 ft.).

Whole body depressed, finely pubescent. General colour orange, often shaded with black on various body parts; elytra and wings black.

Male: Head triangular, transverse, obscurly punctate, sutures obsolete, hind margin emarginate in middle. Eyes only slightly shorter than the post-ocular area. Antennae partly broken (left antenna missing, on the right side only 14 segments remaining); 1st stout, gently expanded anteriorly, shorter than the distance between the antennal bases and longer than eye; 2nd small, about as long as broad; 3rd long, slender; 4th stout, gently expanded anteriorly; 5th slightly longer than the preceding; 7th equal to 3rd but stouter, beyond this segments gradually thinning and increasing in length distally. Pronotum smooth, longer than broad, anteriorly convex, forming a sort of neck, sides depressed, straight, parallel, hind margin subtruncate, median sulcus distinct; prozona weakly raised and metazona depressed. Legs normal. Elytra well developed, obscurely punctate; a small triangular scutellum present. Wings normal, of same texture as the elytra. Abdomen almost parallel sided, faintly punctate, lateral tubercles on 3rd and 4th tergites obsolete, sides of segments convex. Penultimate sternite broadly rounded posteriorly with a faint emargination in middle. Ultimate tergite transverse, almost smooth, medially depressed, laterally compressed with dorsal border sharp, hind margin almost straight. Pygidium vertical, convex above, transverse, narrowed apically with a faint tubercle in middle. Forceps remote at base, sickle-shaped, apices crossing, pointed, trigonal in basal one third, afterwards depressed, armed internally with a sharp triangular tooth at about middle with its tip bent downwards. Genitalia with parameres narrow, a little over three times longer than broad, almost of uniform width throughout, apex obtuse, distal lobes with a short and curved virga.

Female: Agrees with males in most characters except that the penultimate sternite and ultimate tergite narrowed posteriorly; pygidium vertical, convex above, but concave in middle basally, hind margin somewhat undulate; forceps with branches, depressed, straight, tapering apically, internal margin dorsally forming a sharp serrated flange terminating into a triangular tooth in middle, ventral margin serrated.
**Platylabia nathani** Srivastava, Holotype Male; 1. Dorsal view; 2. Genitalia; Paratype Female; 3. Ultimate tergite and forceps.

**Types**: Holotype Male (genitalia mounted between two coverslips and pinned with the specimen), Paratype 1 Female, in Z.S.I.

**Distribution**: Known from type locality only.

**Platylabia bridlei** Srivastava

(Figs.4-9)

Form depressed, finely pubescent. General body colour brownish black, head, pronotum, elytra and wings black; antennae fuscous brown with one or two preapical segments whitish; legs blackish brown; a few apical tergites and forceps brownish.

Male: Head transverse, smooth, hind margin emarginate, sutures obsolete. Eyes distinctly shorter than the post-ocular length. Antennae 24-segmented or more (appear to be partly broken, only 24 segments, on the left side and 18 segments on the right present); 2nd small, shape of remaining segments similar to preceding species. Pronotum longer than broad, anteriorly convex, sides depressed but convex, hind margin subtruncate, median sulcus distinct; prozona weakly raised and metazona depressed. Elytra normal, meeting along the median line; a triangular scutellum visible. Wings abbreviated, scarcely projecting beyond te elytra as narrow lateral lobes. Legs normal. Abdomen depressed, gradually enlarging from base to apex,
depressed, thickly pubescent, smooth, sides of segments convex. Penultimate sternite broadly rounded with a faint emargination in middle. Ultimate tergite transverse, obscurely punctate, depressed along the median line, sides compressed, hind margin almost straight. Pygidium vertical, strongly transverse, depressed, narrowed posteriorly, hind margin straight. Forceps sickle-shaped, trigonal in basal one third, apices pointed and crossing, internally armed at middle with a sharp, oblique flange, terminated at both ends by sharp tooth. Genitalia with parameres broad, a little over two times longer than broad, a faint tubercle present apically close to inner apical angle; distal lobes with a stout, tubular virga and an additional chitinious rod.

Female: Agrees with male in most characters except that the penultimate sternite and ultimate tergite narrowed posteriorly, latter striate near hind margin; pygidium weakly transverse, vertical; forceps depressed, almost straight, internally armed at middle with a triangular tooth and margin dorsally as well as ventrally serrated.

Types: Holotype Male (genitalia mounted between two coverslips and pinned with the specimens), Paratype 1 Female in Z.S.I.

Remarks: Some variations in the relative length of antennal segments 4th to 7th of both sides have been noted (figs. 5, 6) in the Holotype.

Distribution: Known from type locality only.

Subfamily TITANOLABIDINAE

(Type genus—Titanolabis Burr, 1910 = Homoeolabis Borelli, 1911).

Remarks: This subfamily can be easily separated from other subfamilies by the shape of sternal plates especially mesosternum being oval and metasternum tongue shaped posteriorly between hind coxae. The above characters are considered of value at suprageneric level in this work.

Sakai (1987, Vol. xx, p. 2266) considers this subfamily similar to Anisolabidiae on basis of male genitalia but he overlooked the importance of sternal plates as much more stable taxonomic character.

Genus Titanolabis Burr

Build very stout, size medium to large. Head globose, frons convex with faint sutures. Antennae stout, 11-segmented, basal segment stout, about as long as the distance between antennal bases; 2nd short, about as long as broad; 3rd long; 4th subclavate, shorter than 3rd; 5th longer than preceding, 6th onwards slightly increasing in length. Elytra may be present as narrow, lateral ovate flaps on mesonotum or absent. Ultimate tergite and forceps almost identical in both sexes. Genitalia with parameres short, somewhat similar to *Anisolabis* Fieber, about four and half times longer than broad and distal lobes about as long or distinctly longer than the proparameres.

**Distribution**: Oriental and Australian Regions.

**Titanolabis maindroni** (Borelli)

(Figs. 10-14)

**Labidurodes orientalis** Ramamurthi, 1968 *Zool. Anz.*, 181 (1-2) : 130, figs. 1–3 (Male, Female; India : Karnataka, Coimbatore)—*syn.n.*

General colour blackish brown, mouth parts, antennae and legs light yellowish brown.

Male: Head globose, convex above, smooth, sutures fine. Eyes prominent, only slightly shorter than the post-ocular area. Antennae stout, 11-segmented, 1st stout, narrowed basally, about as long as the distance between antennal bases; 2nd short, about as long as broad; 3rd long and slender; 4th stouter, subclavate and shorter than the preceding; 5th stout, longer than the preceding; 6th onwards gradually thinning and increasing in length, each segment narrowed basally. Pronotum longer than broad, widened posteriorly, all margins straight, sometimes hind margin subtruncate; prozona tumid, differentiated from weakly convex metazona by a transverse depression, median sulcus well marked on prozona and faint on metazona. Mesonotum transverse, smooth, hind margin briefly rounded, elytra present as narrow, ovate, lateral flaps. Metanotum transverse, smooth, hind margin broadly & faintly sinuate. Prosternum longer than broad, gently constricted laterally in posterior one third, hind margin

truncate. Mesosternum about as long as broad, broadest near base, narrowed apically with hind margin convex and metasternum oval, comparatively broader in basal half but produced as a narrow tongue shaped lobe between hind coxae. Legs short and stout. Abdomen spindle shaped, finely punctuated, convex, sides of segments 6-9 obtuse angled posteriorly and finely tuberculated. Penultimate sternite smooth, transverse, posterior margin broadly rounded but obtusely produced in middle. Ultimate tergite transverse, moderately convex above, gently depressed posteriorly in middle and the area above the bases of forceps striated, sides straight, hind margin between the branches of forceps truncate and laterally oblique. Forceps stout, subcontiguous, trigonal at base above, afterwards depressed, tapering apically, almost straight in basal half, afterwards gently incurved with apices hooked, crossing or touching and turned upwards, inner margin finely serrated. Genitalia with parameres narrow, about one third as broad as long; tip obtuse; distal lobes with a fine virga.
Female: Agrees with males in most characters except that the penultimate sternite narrowed posteriorly.

*Types:* Holotype male of *Homoeolabis maidroni* Borelli, 1911 at MIZT.

Holotype Male, Allotype Female and Paratypes 1 Male and 1 female of *Labidurodes orientalis* Ramamurthi, 1968 stated to be in the authors collection.

*Distribution:* INDIA: Orissa, Karnataka, Tamilnadu, Pondicherry and Kerala. Also known from Sri Lanka.

*Remarks:* This species appears to be well distributed in Peninsular India. Both sexes are remarkably similar in appearance and the globose head is strikingly different from other Anisolabids.

*Labidurodes orientalis* Ramamurthi, agrees in most of the external features and male genitalia with this species and is considered here as a synonym.

**Subfamily ANISOLABIDINAE**

Build stout. Antennae multisegmented, generally having 15 to 22 segments. Prosternum longer than broad; metasternum quadrate with hind margin briefly convex and metasternum transverse, narrowed posteriorly with hind margin truncate. Elytra and wings well developed, abbreviated or wanting. Legs short and stout. Forceps
short, stout and trigonal in basal half, in males, generally incurved in apical half and in females, simple and straight. Male genitalia with proparameres fused at base and separated apically; left distal lobe generally short, directed apically and right distal lobe elongated, directed basally, often chitinous pads with fine teeth present; virga may be discernible or absent.

_Type genus_: _Anisolabis_ Fieber, 1853.

_Distribution_: All over the world but more common in tropical and subtropical parts.

**Key to the genera (based on males)**
(Partly modified after Srivastava 1999)

1(2). Parameres long, over ten times longer than broad, narrow, sometimes broader at base ..........................................................................................................._EPILANDEX_ Hebard

Genus Epilaxend Hebard

Size small, build stout. Antennae 17-segmented; 1st segment about as long as the distance between antennal bases; 2 short, about as long as broad; 3rd long & cylindrical; 4th & 5th subconical, almost equal or a trifle longer that 4th but both shorter than 3rd; 6th onwards segments gradually increasing in length distally but each one narrowed at base and expanded apically. Elytra and wings well developed but wings sometimes wanting. Prosternum longer than broad; mesosternum quadrate, convex posteriorly; metasternum transverse, narrowed posteriorly between hind coxae with hind margin truncate. Male genitalia with parameres more than 10 times longer than its width, narrowed apically with tip acuminate often recurved; distal lobes well developed, virga tubular, at base with accessory chitinous plates.

Type species : Landex burri Borelli, 1921.

Distribution : Oriental and Australian Regions.

Remarks : The type Female of Labidura femoralis Dohrn, 1863 from Sri Lanka preserved at IZAP was examined. On the basis of antennal segments it can be said with certainty that it is a member of Euborellia Burr, 1910 and distinct from the females of Epilaxend burri (Borelli, 1921).

Epilaxend burri (Borelli)
(Figs. 15-22)

Labidura femoralis (pars); Dubrony (néc Dohrn), 1879, Annali Mus. civ. Stor. nat. Giacomo Doria, 14 : 353, fig (1 male; Australia : Somerset)

*Epilandex bazyluki* Steinmann, 1979, *Folia ent. hung.*, 32 : 155, figs. 15–17 (Male; Sri Lanka)—Syn. n.
General colour blackish brown, basal portion of 1st and 3rd antennal segments and mouth parts yellow; legs yellow with femora in most part brownish; head, pronotum and elytra blackish brown; abdominal tergites light brown along the posterior margin, sometimes, in females, laterally above with a patch of yellow on tergites; forceps somewhat reddish brown.

Male: Head slightly longer than broad. Frons, convex, sutures fine but distinct, hind margin feebly emarginate in middle. Eyes prominent but shorter than post-ocular length. Antennae typical of the genus. Pronotum about as long as broad, gently widened posteriorly with hind margin broadly rounded, sides straight, prozona raised and well differentiated from weakly raised metazona. Elytra well developed, one and half times longer than the pronotum, coriaceous, meeting along the median line, hind margin obliquely truncate. Legs long and slender, hind femora stout; tibiae compressed, in apical half grooved above; tarsi with 1st segment slender, almost equal to the combined length of 2nd and 3rd, claw without an arolium, underside clad with thick and fine pubescence. Abdomen gradually enlarging posteriorly up to 9th tergite, afterwards narrowing, tergites convex, obscurely reticulated, sides of segments 7th to 9th acutely pointed posteriorly, with or without an oblique carina. Penultimate sternite transverse with hind margin convex and produced in middle with a minute point having a faint ridge. Ultimate tergite transverse, smooth, moderately convex above in basal half and sloping backwards, laterally above with a convexity, gently narrowed backwards, hind margin in middle feebly concave, laterally oblique. Forceps stout, almost straight in basal half, afterwards gradually tapering and incurved with apices hooked, internally with one or two large rounded teeth, followed by fine serrations, branches in basal half trigonal, afterwards depressed. Genitalia with parameres more than 10 times longer than broad, strongly narrowed apically with tip recurved; virga distinct, at base accessory chitinous plates present.

Female: Agrees with male in most characters except that sides of abdominal segments 7th to 9th acute posteriorly but without carina; penultimate sternite obtuse in middle posteriorly; ultimate tergite strongly narrowed backwards and forceps simple and straight.

Measurements: (in mm)

Types: 1 Male, 1 Female of *Landex burri* Borelli, 1921 at MNHP.

Holotype Male of *Epilandex undulata* Ramamurthi, 1963 with the author.

Holotype Male of *Epilandex bazyluki* Steinmann, 1977 at IZAP.

Distribution: India (Tamil Nadu), Sri Lanka and Thailand. Also reported from Australia (Srivastava, 1987).
**Remarks**: Srivastava (1982b) has recorded some variation regarding the absence of oblique carina on the sides of abdominal segments, in males, from India (Tamil Nadu) and the shape of parameres.

In view of the above *Epilandex bazyluki* Steinmann, described, on a macropterous male, from Sri Lanka is considered here as a synonym.

This species can be easily separated from the members of the genus *Euborellia* by the shape conical or subconical antennal segments and characteristic external build, especially sides of abdominal segments 7th to 9th.

It is represented by 2 Males, 1 Female from India: Tamil Nadu, Kodai Kanal dist., Perumalmalai, ca 5500 ft., in the collections of the Zoological Survey of India, Calcutta.

**Genus**: *Aborolabis* Srivastava

**Male**: Size medium, surface pilose. Head triangular, sutures distinct, hind margin feebly sinuate in middle. Antennae 15 to 19 segmented, 1st segment equal to combined length of 2nd and 3rd; 3rd long and cylindrical; 4th shorter than preceding, 6th onwards segments increasing in length. Eyes shorter than post-ocular length. Pronotum quadrate, gently widened posteriorly with hind margin truncate or briefly rounded. Mesosternum with hind margin briefly rounded and metasternum truncate. Apterous, sometimes elytra may be abbreviated and wings obsolete or both well developed. Abdomen dilated in middle or gently so. sides of segments 6th to 9th acute angled posteriorly, ecarinate or carinate, sometimes with a linear convexity on certain segments. Penultimate sternite with hind margin truncate, faintly sinuate in middle or briefly rounded. Forceps strongly or gently incurved in apical half. Genitalia with parameres three times longer than broad, gently dilated at about middle, slightly narrowed apically, armed at base with a tooth of variable size, often as large as the paramere itself; distal lobes often provided with longitudinal rows of chitinous teeth.

**Female**: Agrees with male in most characters except that sides of abdominal segments convex posteriorly; penultimate sternite triangular with posterior margin obtuse in middle and forceps with branches simple and straight.

**Type species**: *Anisolabis pervicina* Burr, 1913.

**Distribution**: Oriental (Himalayas and other mountains of North East India) and Palaearctic (Iberian Peninsula and Palaearctic North Africa) Regions.
Remarks: The Genus *Aborolabis* was erected by Srivastava (1969a) with *A. pervicina* (Burr) as its type-species. It is mainly characterised by the presence of a tooth at the base of parameres, in males.

Steinmann (1979), for the first time, presented a revision of the genus and recorded six species from India, South Europe and North Africa.

At present, from the Indian subcontinent six species are known which are distributed in the mountains of North-Western to North-Eastern India, Nepal and Bhutan.

**Key to the species (based on males)**

1(2). Penultimate sternite broadly emarginate posteriorly ........................................... 

................................................................................................................. *A. emarginata* Srivastava

2(1). Penultimate sternite entire or with a faint emargination in middle

3(6). Parameres longer than its inner basal tooth

4(5). Sides of abdominal segments ecarinate; parameres armed internally at base with a minute tooth ................................................. *A. meghalayensis* Srivastava

5(4). Sides of abdominal segments ecarinate (or occasionally with a linear convexity on 8th segment only); parameres armed internally at base with a larger tooth .......................................................................................... *A. nepalensis* (Brindle)

6(3). Parameres about as long as its inner basal tooth

7(8). Sides of abdominal segments ecarinate .......... *A. kalaktangensis* Srivastava

8(7). Sides of certain abdominal segments carinate

9(10). Elytra and wings well developed or former abbreviated and latter absent; sides of abdominal segments 6th to 9th obtuse angled posteriorly, with a linear convexity ................................................................. *A. sikkimensis* Srivastava

10(9). Apterous; sides of abdominal segments 6th to 9th acute angled posteriorly, with a sharp or faint carina .......................................................... *A. pervicina* (Burr)

*Aborolabis emarginata* Srivastava

(Figs. 23–25)

General colour blackish brown; antennae with three basal and one or two antepapical segments yellow. Pronotum yellow on sides; legs yellow but femora banded with brown in middle and forceps blackish apically.

Male: Head as long as broad, frons tumid and posterior margin truncate. Eyes shorter than the post-ocular length. Antennae 16-segmented or more, 1st gently expanded apically, stout, slightly shorter than 2nd to 4th together; 2nd small; 3rd long and slender; 4th and 5th subclavate and equal, remaining gradually increasing in length distally, each segment narrowed at base, slightly expanded apically. Pronotum slightly expanded posteriorly, hind margin subtruncated, laterally a little reflexed, median sulcus faint; pro- and metazona little differentiated. Elytra and wings wanting. Legs typical of the genus, femora stout. Abdomen convex, finely punctate, narrowed basally, sides of segments 6th to 9th acute angled posteriorly, carina present on 7th and 8th only. Penultimate sternite with posterior margin broadly emarginate. Ultimate tergite transverse, sparsely punctulate, gently narrowed posteriorly, median sulcus short, hind margin feebly emarginate in middle. Forceps with branches sub-contiguous, tapering apically, trigonal in basal one third, afterwards somewhat depressed, weakly asymmetrical, left branch almost straight, right branch more curved and crossing over the left, internal margin crenulate. Genitalia with parameres broad, basal tooth shorter than the paremere.

Female: Agrees with male but sides of abdominal segments posteriorly convex and ecarinate; penultimate sternite obtuse posteriorly and forceps simple and straight with apices gently incurved.

Types: Holotype Male, Allotype Female in Z.S.I.

Distribution: India (Arunachal Pradesh and Meghalaya).

Remarks: This species differs from the *A. meghalayaensis* Srivastava, in having the penultimate sternite distinctly emarginate posteriorly and the parameres greatly dilated in middle with inner basal tooth comparatively larger.

**Aborolabis meghalayaensis** Srivastava

General colour shining dark brown with traces of red on some tergites in middle; mouth parts, a few basal antennal segments, sides of pronotum and legs yellowish but femora banded with black in middle.

Male: Head about as long as broad, smooth, sutures finely marked, hind margin feebly emarginate in middle. Eyes shorter than post-ocular length. Antennae–12 segmented or more (partly damaged), basal segment about as long as the distance between antennal bases; 2nd small; 3rd long, cylindrical, about as long as the combined length of 4th and 5th which are subconical, remaining gradually increasing in length distally and each narrowed basally. Pronotum smooth, as long as broad, all margins straight, sides gently reflexed in middle, widened posteriorly with angles rounded, median sulcus faintly marked; pro-and metazona little differentiated. Legs normal. Meso-and metanotum smooth, transverse, latter broadly emarginate posteriorly. Abdomen moderately convex, punctate, punctuation slightly faint in middle of tergites, gradually widening posteriorly, sides of segments 5th to 9th rugosely striate. Penultimate sternite punctate, triangular, scarcely emarginate in middle posteriorly; manubrium three times longer than the sternite with apex dilated. Ultimate tergite transverse, sparsly punctate, sloping backwards, median sulcus distinct, laterally an oblique carina present and more strongly punctate. Forceps remote at base, triangular in basal one third, afterwards depressed, tapering, in apical third gently curved with apices hooked, internal margin finely serrated. Genitalia as seen in figs. 30 and 31.

Female: Agrees with males in most characters except that sides of abdominal segments obtusely convex; penultimate sternite triangular with hind margin entire; ultimate tergite comparatively narrowed posteriorly and forceps with branches subcontiguous and straight.

Types: Holotype Male, Paratype 1 Female deposited in Z.S.I.

Distribution: India: Meghalaya (East Khasi Hills dist.; Cherrapunji, 1300m); known from the type locality.

Remarks: This species comes close to Aborolabis nepalensis (Brindle) in having the sides of abdominal segments ecarinate but differs in having the pronotum about
as long as broad (vs transverse in *A. nepalensis*); sides of segments 5th to 9th obtuse angled (vs 7th to 9th acute angled) and parameres armed at base with a minute tooth (vs armed with a large tooth).

**Aborolabis nepalensis** (Brindle)

(Figs. 32–35)

*Anisolabis nepalensis* Brindle, 1974, *Senckenbergiana biol.*, **55** (1/3) : 148, fig. 4 (Male, Female; Nepal).

General colour dark brownish black; antennae with one or two pre-apical segments yellow, apices ringed with brownish black; legs yellow, femora dark brownish black in basal two thirds.

Male: Head smooth, transverse, scarcely emarginate in middle posteriorly, frons convex, sutures fine but visible. Antennae 17-segmented or more (since apical ones tend to break off easily), 1st basal segment, shorter than the distance between antennal bases; 2nd short, transverse; 3rd cylindrical, a little over 2 times longer than broad; 4th slightly longer than broad; 5th slightly longer than 4th but shorter than 3rd; 6th about as long as 3rd, remaining gradually increasing in length distally, short pubescence present on all segments except basal two segments. Eyes shorter than the post-ocular length. Pronotum transverse, gently widened posteriorly with margin subtruncate, lateral margin straight, gently reflexed, median sulcus faintly marked; pro- and metazona little differentiated. Mesonotum straight and metanotum emarginate posteriorly. Legs short, femora glabrous but with sparse setae, tibiae with relatively long yellow hairs ventrally and towards apices; tarsi with ventral hairs but on basal segment ventrally with a double row of thick yellow hairs. Abdomen broad, moderately convex, lateral tubercles on 3rd and 4th tergites present, gradually enlarging posteriorly up to 9th tergite, finely punctulate, sides of 6th segment obtuse angled posteriorly and obscurely punctulate and segments 7th to 9th acute angled posteriorly, rugosely striate but without carina. Penultimate sternite broadly triangular, hind margin in middle subtruncate or scarcely emarginate. Ultimate tergite transverse, longitudinal stripes of smooth and puctulated areas alternating, convex above in apical half, sloping backwards, on sides oblique carina present, hind margin faintly emarginate in middle, laterally above the bases of forceps oblique. Forceps remote at base, trigonal above in basal one third, afterwards depressed, tapering apically, apices gently hooked, asymmetrical, internal margin crenulated. Genitalia with parameres broad, at base with a small triangular tooth, each paramere with an oblique, dark and membranous fold in middle.

Female: Agrees with male in most characters except that sides of abdominal segments not rugose; ultimate tergite narrowed posteriorly; penultimate sternite triangular, obtuse posteriorly and forceps simple and straight.
Figs. 32-35: Aborolabis nepalensis (Brindle), Male; 32. Dorsal view; 33. A few basal antennal segments; 34. Sides of abdominal segments; 35. Genitalia (one paramere missing).

Types: Holotype Male, Allotype Female and Paratypes 2 Females in SMF and Paratypes 1 Male, 1 Female in MM.

Distribution: Nepal.

Remarks: The sides of abdominal segments 7th to 9th, in Males, are generally acute angled posteriorly and rugosely striate. Sometimes a lineal convexity (not carina) is present. However, in 1 Male from Nepal, Aghore (Srivastava, 1990) sides of abdominal segments are smooth and without any convexity.
This species is externally close to *Aborolabis meghalayensis* Srivastava, but differ by shape and texture of sides of abdominal segments and the internal basal tooth of paramere, in Males.

*Aborolabis kalaktangensis* Srivastava
(Figs. 36–40)

General colour brownish with traces of black on abdomen only; antennae with 2nd segment yellowish, remaining brownish yellow; legs brownish yellow, femora basally dark brown. Build slender.

Male : Head triangular, frons raised, sutures faint, hind margin gently sinuate in middle. Eyes distinctly shorter than post-ocular area. Antennae 17-segmented, 1st segment stout, narrowed basally and expanded apically, about as long as the distance between bases of antennae; 2nd short, about as broad as long; 3rd a little over twice as long as broad, cylindrical, gently expanded apically; 4th shorter than preceding, slightly longer than broad; 5th slightly longer than 4th and shorter than 3rd; 6th onwards gradually increasing in length and slightly narrowed basally. Pronotum quadrate, all margins straight, postero-lateral angles gently rounded and sides reflexed, median suture well marked, prozona tumid and metazona weakly depressed. Meso- and metanotum transverse, former with hind margin truncate and latter broadly emarginate. Elytra and wings wanting. Legs with femora stout; tibae basally with brownish yellow hairs; tarsi with 1st (basal) segment almost equal to 2nd and 3rd together, 1st segment with two rows thick yellow hairs on under side. Abdomen cylindrical, almost parallel sided or feebly dilated in middle, weakly convex, obscurely punctulate, sides of segments 6th to 9th acute angled posteriorly but smooth and without any ridge. Penultimate sternite somewhat oval, hind margin feebly rounded; manubrium slightly more than double the length of sternite and apical end dilated. Ultimate tergite weakly transverse, smooth, convex above laterally in basal half, gently sloping backwards, median sulcus distinct, oblique striae present in the area just above the base of forceps, hind margin trisinuate, laterally oblique. Genitalia with parameres three times longer than broad, narrowed apically, basal tooth internally, only slightly shorter in length or of the same size; distal lobes without virga or teeth.

Female : Agrees with male in most characters except that the sides of abdominal segments convex; penultimate sternite with hind margin obtusely rounded and forceps almost straight.

**Types**: Holotype Male, Paratypes 5 Females in Z.S.I.

**Distribution**: India: Arunachal Pradesh (Kameng and Subansiri dists.); Sikkim (Rangpo) and Meghalaya (East Khasi Hills dist.).

**Remarks**: This species comes close *A. pervicina* (Burr) and *A. sikkimensis* Srivastava but differs from both in having slender build, uniformly coloured femora and ecarinate sides of abdominal segments.
**Aborolabis sikkimensis** Srivastava
(Figs. 41–48)

General colour dark brownish black; legs brownish yellow, femora banded with black in basal half; antennae with basal segment annulated with a yellow ring, 2nd and one or two pre-apical segments yellow.

Male : Head smooth, convex, slightly longer than broad, hind margin scarcely emarginate in middle, sutures faint. Eyes prominent, shorter than post-ocular length. Antennae 17-segmented (in Holotype Male, antennae of left side missing and on the right 14 segments remaining), basal segment stout, expanded apically, slightly shorter than the distance between antennal bases; 2nd short, about as long as broad; 3rd long and cylindrical; 4th a trifle shorter than 5th; 6th onwards segments slightly increasing in length and becoming less stouter. Pronotum about as long as broad, gently expanded posteriorly, sides straight, hind margin convex, median sulcus faint, prozona raised and metazona depressed; in Paratype Male pronotum more expanded posteriorly. Elytra well developed, meeting along the middle line, hind margin convex, shoulder weak; in Paratype Male elytra abbreviated, shorter than pronotum in length. Wings well developed. Legs typical of the genus. Abdomen spindle shaped, weakly convex, finely punctulated, sides of abdominal segments 6th to 9th obtuse angled, rugosely punctate posteriorly, with a linear convexity but weaker on 5th and 9th segments. Penultimate sternite truncate posteriorly. Ultimate tergite transverse, gently contracted posteriorly, finely punctulated, weakly depressed, gently sloping backwards with a slight depression in middle, median sulcus distinct and short, sides straight, hind margin almost straight in middle, gently concave and oblique laterally. Forceps with branches subcontiguous, broader at base, tapering apically, trigonal in basal 1/3, afterwards depressed, left branch almost straight except in apical 1/4 gently curved, right branch strongly curved in middle, apices hooked, internal margin crenulated. Genitalia with parameres armed internally at base with a large triangular tooth, distal lobes without denticulated pads.

Female : Agrees with males in most characters except that sides of abdominal segments convex and ecarinate; penultimate sternite obtuse posteriorly; ultimate tergite strongly narrowed posteriorly and forceps simple and straight.

**Types** : Holotype Male (macropterous), Paratype 1 Male (brchyppterous) and Paratype 1 Female (macropterous) in Z.S.I.
Figs. 41-48: *Aborolabis sikkimensis* Srivastava, Holotype Male; 41. Anterior portion of body; 42. Hind portion of penultimate sternite; 43. Ultimate tergite and forceps; 44. Genitalia; Paratype Male (brachypterous); 45. Anterior portion of body; 46. Hind portion of penultimate sternite; 47. Genitalia; Paratype Female; 48. Ultimate tergite and forceps.
Distribution: India: Sikkim (Rangpo) and Meghalaya (West Khasi Hills dist.).

Remarks: This species can be easily separated from all the other known species of the genus by its slender build; presence of elytra and wings and sides of abdominal segments 6th to 9th rugosely punctate, obtuse angled posteriorly with a linear convexity, almost obsolete on 6th and 9th.

**Aborolabis pervicina** (Burr)

(Figs. 49–56)

Male: General colour shining reddish to blackish brown. Legs yellowish brown; femora and tibiae banded with black.

Head triangular, convex, sutures faint, hind margin faintly emarginate in middle. Eyes shorter than the post-ocular area. Antennae 19-segmented, 1st segment equal to combined length of 2nd to 4th; 2nd short, about as long as broad; 3rd long; 4th about half as long as the preceding and equal to 5th, rest gradually increasing in length distally. Pronotum quadrate, anterior and lateral margins straight, gently widened posteriorly with margin truncate or briefly convex, median suture faint or well marked; prozona raised and metazona depressed. Apterous. Legs typical of the genus. Abdomen spindle shaped, moderately convex above, punctate or punctulate, sides of abdominal segments 6th to 9th acute angled posteriorly, striate and provided

with a median carina, sparse pubescence present on under side only. Penultimate sternite broadly rounded, punctulate, posterior margin truncate. Ultimate tergite transverse, sparsely punctate, disc weakly convex, sides rugose with a longitudinal fold, posteriorly in middle with a faint depression, striolate above the bases of forceps, median sulcus short. Forceps with branches remote and dilated at base, trigonal with ridge present in basal 1/3 to 1/2, afterwards depressed, tapering apically with tip gently hooked and pointed, asymmetrical, right branch more curved than the left, inner margin crenulate. Genitalia with parameres three times longer than broad, gently dilated at about middle and narrowed towards apex, tip rounded, outer margin convex, internally at base armed with a triangular tooth, almost of same size as paramere with tip pointed and hooked; distal lobes apically with rows of minute teeth.
Female: Agrees with males in most characters except that sides of abdominal segments posteriorly rounded, almost smooth and ecarinate; penultimate sternite obtusely pointed posteriorly; ultimate tergite narrowed posteriorly and forceps simple and straight.

**Types**: Nonomotype Male of *Anisolabis pervicina* Burr in Z.S.I.

Holotype Male, Paratypes 2 Females of *Aborolabis nigrescens* Brindle in SMF and Paratype 1 Male in MM.

**Distribution**: India: W.B. (Darjeeling Dist.); Sikkim, Assam, Meghalaya, Arunachal Pradesh and Himachal Pradesh.

Also recorded from Bhutan and Nepal. It has been reported in Himalayas between altitudes 100 m and a little over 3500 m.

**Remarks**: This species occurs in large numbers under stones or bark of logs and standing trees.

In a large population often some specimens with weaker forms of forceps i.e., branches subcontiguous and almost straight with apices hooked, are met with. It is noticed that in such specimens the median carina on the sides abdominal segments from 6th to 9th is poorly marked. Besides, in males, with normal forceps (strongly asymmetrical) the sides abdominal segments 6th to 9th are striate and strongly carinate and on 5th segment only a small tubercle or convexity at the posterior end is present.

**Genus**: *Euborellia* Burr

Small to medium (8.0–14.0 mm); build slender. General colour black to blackish brown; antennae with one or two pre-apical segments sometimes pale; legs generally uniformly coloured but femora sometimes banded with black in basal half. Head generally convex; eyes may be small or large but generally shorter than post-ocular length; antennae moniliform. Pronotum usually longer than broad, often as long as broad, widened posteriorly. Apterous, sometimes elytra abbreviated as narrow lateral flaps, rarely elytra and wings well developed (rarely more than one form represented intraspecifically). Meso- and metasternum truncate posteriorly. Abdomen weakly depressed, slightly dilated in middle, sides of segments, in Males, convex or acute angled posteriorly with or without carina. Penultimate sternite rounded, truncate or emarginate posteriorly. Forceps short, stout, trigonal above at base, strongly or weakly asymmetrical, in Males, and simple and straight in Females. Male genitalia with parameres almost square or sometimes slightly longer than broad with external apical angle rounded or a little projecting, an oblique narrow membranous fold from inner apical angle to basal angle present; distal lobes with or without chitinous pads; virga may be distinct or invisible.

Type species: Forficesila moesta Gené in Serville, 1839.

Distribution: World wides but dominant in Ethiopian and Oriental Regions.

Remarks: In the Indian subcontinent eight species are known and well distributed all over the area. Besides two species, namely, E. kumoensis and E. askotensis described by Gangola (1968) from kumaon Hills, (India: Uttar Pradesh) are treated as doubtful species and are not included in the key to species.

The members of the genus occur in a variety of habitat but are more common under stones with dead and decaying matter. Sometimes these are attracted to light also.
Key to the species (based on Males)

1(8). Usually apterous

2(5). Sides of abdominal segments ecarinate

3(4). Build slender; pronotum with a slight emargination in middle posteriorly; penultimate sternite with posterior margin broadly rounded; parameres without a distinct inner apical concavity......................... \textit{E. dattai} Srivastava

4(3). Build stout; pronotum with posterior margin entire; penultimate sternite narrowed posteriorly, with margin in middle scarcely emarginate; parameres with an inner apical concavity ....................... \textit{E. rajasthanensis} Srivastava

5(2). Sides of abdominal segments carinate

6(7). Legs yellow, often femora with a broad brownish or blackish band; parameres with external apical angle convex ........................................ \textit{E. annulipes} (Lucas)

7(6). Legs with femora uniform yellow; parameres with external apical angle acute, a little projecting.................................................. \textit{E. compressa} (Borelli)

8(1). Elytra and wings well developed, often former abbreviated and latter absent

9(12). Elytra and wings well developed.

10(11). Sides of abdominal segments 6th to 9th ecarinate ........ \textit{E. plebeja} (Dohrn)

11(10). Sides of abdominal segments 7th to 9th carinate .... \textit{E. femoralis} (Dohrn)

12(9). Elytra present as narrow lateral ovate flaps on mesonotum; wings wanting

13(14). Size larger (10–13 mm); sides of abdominal segments recurved; parameres with external apical angle a little projecting .............. \textit{E. annandalei} Burr

14(13). Size smaller (8–11 mm); sides of abdominal segments not recurved; parameres with external apical angle not projecting

15(16). Parameres with a distinct inner apical concavity ... \textit{E. annulata} (Fabricius)

16(15). Parameres without a distinct inner apical concavity

17(18). Sides of abdominal segments 6t to 9th acute angled and carinate; fine virga discernible; paramere with upper margin straight.................................................. \textit{E. abbreviata} Srivastava

18(17). Sides of abdominal segments 6t to 9th obtuse angled and ecarinate; virga not visible; paramere wit upper margin convex ..... \textit{E. manipurensis} Srivastava

\textit{Euborellia dattai} Srivastava

(Figs. 57–60)

Figs. 57-60 : *Euborellia dattai* Srivastava, Male; 57. Dorsal view; 58. A few basal antennal segments; 59. Hind portion of penultimate sternite; 60. Genitalia. (Figs. 57, 59 and 60 are from Holotype Male and fig. 58 from Paratype Male).

General colour yellowish brown. Legs yellowish with femora brown. Pronotum yellowish on sides and posteriorly. Antennae with one or two preapical segments whitish.

Male : Head smooth, globose, sutures obliterated, frons and occiput convex; widest in the region of eyes. Eyes whitish, slightly shorter than post-ocular area. Antennae 17–segmented, 1st stout, gently expanded apically, shorter than the distance between antennal bases; 2nd short, about as long as broad; 3rd and 4th subclavate, almost equal in length; 5th slightly longer than preceding two segments, remaining gently narrowed basally and gradually increasing in length distally, apical segments thin
and rod shaped. Pronotum smooth, slightly longer than broad, anterior margin straight, sides reflexed, concave in middle, slightly diverging posteriorly, posterolateral angles well rounded, hind margin briefly rounded with a faint emargination in middle, median sulcus distinct, prozona raised and well differentiated from flat metazona. Elytra and wings absent. Meso- and metanotum about half as long as pronotum, metanotum with hind margin deeply emarginate in middle. Legs typical of the genus. Abdomen long and slender, scarcely enlarged in middle, smooth, fine yellow pubescence present, sides of segments smooth, ecarinate and obtuse posteriorly. Penultimate sternite transverse, posterior margin broadly rounded. Ultimate tergite transverse, smooth, fine pubescence present, gently sloping and narrowing backwards, median sulcus short, distinct in posterior half only, faintly striate above the roots of forceps, hind margin trisinute, laterally oblique. Forceps subcontiguous, trigonal in basal one fourth, afterwards depressed, branches almost straight, tapering apically, gently incurved in apical one third, apices gently hooked, pointed and crossing each other. Genitalia with parameres slightly longer than broad, external apical angle and margin convex; distal lobes apically with chitinous denticulated pads.

Female: Agrees with male in most characters except that the head is comparatively less convex with sutures distinct and eyes less prominent.

**Types**: Holotype male, Paratypes 2 Females and 2 nymphs desposited in the Z.S.I.

**Distribution**: India: Rajasthan; known from the type locality only.

**Remarks**: This species can be easily separated from other known species in having the hind margin of pronotum, in middle, emarginate; penultimate sternite broadly rounded posteriorly and parameres slightly longer than broad.

*Euborellia rajasthanensis* Srivastava  
(Figs. 60,61A–63)

Male: General colour blackish brown; pronotum laterally and leg yellowish brown.

Head triangular, smooth, shining, frons and occiput weakly raised, sutures faint, hind margin emarginate in middle. Eyes black, shorter than post-ocular area. Antennae

(most of the segments broken off in the Holotype Male) with only right basal segment remaining. Pronotum slightly longer than broad, gently widened posteriorly, hind margin rounded, lateral margin straight, weakly reflexed; prozona convex, metazona depressed, median sulcus faintly marked on prozona. Meso- and metanotum smooth, latter with hind margin concave. Legs typical of the genus. Abdomen obscurely punctulate, very slightly dilated in middle, sides of segments 6th to 9th rugosely punctate, ecarinate and acute posteriorly. Penultimate sternite faintly punctulate, narrowed apically with hind margin scarcely emarginate in middle. Ultimate tergite transverse, punctulate, gently contracted posteriorly, median suture short, distinct in posterior half only, faintly tumid above the roots of forceps, hind margin trisinuate, oblique laterally. Forceps stout, contiguous, trigonal in basal one third, afterwards depressed, tapering apically, branches almost straight in basal two thirds, gently incurved in apical one third with right branch slightly more incurved than the left and crossing over it a little before apex, apices hooked and pointed, internal margin serrated. Genitalia with parameres short and broad, inner apical concavity distinct; distal lobes apically with chitinous pads.
Female: Agrees with males in most characters except that penultimate sternite with posterior margin obtuse in middle; ultimate tergite comparatively narrowed posteriorly and forceps simple and straight. Antennae 15-segmented; 2nd about as broad as long; 3rd long, slender; 4th and 5th subclavate, both shorter than the preceding, remaining gradually increasing in length distally.

Measurements: (in mm)

Types: Holotype Male, Paratype 1 Female in ZSI.

Distribution: India (Rajasthan) and Pakistan (Taxilla).

Remarks: This species resembles externally with Euborellia annulipes (Lucas) but differs in being slightly stouter in build; and in Males, sides of abdominal segments are ecarinate and parameres with external apical angle acute and a distinct concavity at inner apical angle.

Euborellia annulipes (Lucas)
(Figs. 64–69)

Forficesila annulipes Lucas, 1847, Annls. Soc. ent. Fr., (2) 5 : 84 (Type Female; France–Introduced); Dohrn, 1864, Sttetin. ent. Ztg., 25 : 290.

Forficula (Labidura) annulipes; Fischer, 1853, Orthoptera Europa,—Leipzig, 69, pl. 6, figs. 6a–c.

Figs. 64-69: *Euborellia annulipes* (Lucas), Male; 64. Anterior portion of body except ultimate tergite and forceps; 65. Posterior half of penultimate sternite; 66. Ultimate tergite and forceps; 67. Genitalia; 68. Paramere enlarged; Female; 69. Ultimate tergite and forceps.

The Fauna of India and the Adjacent Countries

Forficula annulicornis Blanchard, 1852, in Gey, Hist. nat. Chile, Zool. 6 : 10 (Type not mentioned; Chile); Burr, 1911, Genera Insect., 122 : 29 (treated as synonym).

Forficula variicornis Smith, 1876, Ann. Mag. nat. Hist., (4) 17 : 450 (Type and Type locality not mentioned); Burr, 1911, Genera Insect., 122 : 29 (treated as synonym).

Anisolabis antennata Kirby, 1891, J. Linn. Soc. Zool., 23 : 517 (Female; Bermuda); Burr, 1911, Genera Insect., 122 : 29 (treated as synonym).

Anisolabis bormansi Scudder, 1893, Bull. Mus. comp. Zool. Harv., 25 : 5, pl. 1, fig. 1 (Female; Chatham Island); Burr, 1911, Genera Insect., 122 : 29 (treated as synonym).

Anisolabis tripolitana Werner, 1908, Zool. Jb., 27 : 85, Pl. 6, fig. 10 (Male, Female; Type and type locality not given); Steinmann, 1989, World Catalogue of Dermaptera : 263 (proposed as synonym).

Male: General colour shining blackish brown; antennae with basal and a few antepalpical segments yellow, rest greyish brown; pronotum on sides and legs yellow, femora banded with black.

Head, about as long as broad or weakly transverse, smooth, sutures fine but distinct, frons convex, hind margin feebly emarginate in middle; eyes black, prominent, much smaller than post-ocular length. Antennae 16 to 17 segmented, 1st stout, gently expanded apically, shorter than the distance between antennal bases; 2nd short, transverse; 3rd long, a little over twice its width, cylindrical; 4th shorter and stouter than 3rd and expanded apically; 5th almost equal to preceding; 6th almost equal to 3rd, remaining gradually increasing in length distally, except a few apical ones. Elytra and wings generally absent, rarely both well developed. Pronotum smooth, about as long as broad, anteriorly as wide as head, lateral margins straight, gently reflexed in middle, widened posteriorly; median sulcus fine but distinct; prozona convex and well differentiated from flat metazona. Meso- and metanotum transverse, smooth, former posteriorly truncate and latter broadly emarginate. Sternal plates typical of the genus. Legs comparatively short; femora stout; tibae clad with thick and fine hairs, 1st segment (basal) almost equal to combined the length of 2nd and 3rd. Abdomen spindle shaped, weakly depressed, punctulate but punctuation more prominent in posterior half of each tergite, sides of segments 6th to 9th acute angled posteriorly, striate and carinate. Penultimate sternite triangular, posteriorly truncate or faintly emarginate in middle. Ultimate tergite transverse, weakly punctate, convex above in basal half, median sulcus distinct, laterally with rugose or striate linear convexity, hind margin trisinuate, oblique laterally above base of forceps. Forceps with branches remote or subcontiguous, trigonal in basal one third only, afterwards depressed and tapering, right branch more incurved than the left, apices gently hooked and crossing, inner margin finely serrated. Genitalia with parameres broad, about as long broad, external apical angle rounded; distal lobes with denticulated chitinous pads apically; fine virga sometimes visible.
Female: Agrees with males in most characters but differs in having sides of abdominal segments convex and smooth; penultimate sternite obtuse posteriorly; ultimate tergite strongly narrowed posteriorly and forceps simple, contiguous and almost straight except apices.

*Types*: Type Male of *Forficula aequesris* Géné, 1837, repository not known—according to Steinmann (1989a).

Type Female of *Forficesila annulipes* Lucas, 1847, deposited in MHNP—according to Steinmann, (1989a).

Type Male of *Forficula annulicornis* Blanchard in Gay, 1852, repository not known—according to Steinmann (1989a).

Type, sex ?, of *Forficula variicornis* Smith, 1876, repository not known—according to Steinmann (1989a).

Type Female of *Anisolabis antennata* Kirby, 1891, deposited in BMNH.

Type Female of *Anisolabis bormansi* Scudder, 1893, repository not known.

Types: 3 Males and 4 Females of *Anisolabis fallax* Shiraki, 1905, mentioned as present in the collection of Dr. S. Matsumura and Mr. W. Ishida (Shiraki, 1905).

Type Male ? of *Anisolabis tripolitana* Werner, 1908, repository not known—according to Steinmann (1989a).

Type Holotype Male ? immature, Paratype 1 Male, Allotype 8 Females and 6 immature specimens of *Anisolabis nana* Boeseman, 1954 deposited in IZTA.

*Distribution*: India: Tamil Nadu: Anamalainagar, Yercaud Hills, 4500 ft. Naduvatam, Nilgiri Hills, 6000 ft., Coimbatore; Maharashtra: Satara dist., Medha and Yenna Valley; Orissa: Barkuda Island, Chilka Laka, Koraput dist., Jeypore; Madhya Pradesh: Jabalpur, 1600 ft.; West Bengal: 24-Parganas, Purulia, Midnapore, Jalpaiguri and Darjeeling dists., (Darjeeling, 2193 m); Assam; Meghalaya: Garo Hills (Siju Cave, East Garo Hills, West Khasi, Hills); Tripura; Manipur; Arunachal Pradesh; Punjab; Rajasthan: Nagaur dist.; Himachal Pradesh; Uttar Pradesh and Andaman Isls.

In India it is one of the most common species occurring in a variety of habits right from plains to high altitude (ca 2193 m) in mountains.

It is also reported extensively from Pakistan, Nepal, Bhutan, Bangladesh, Myanmar, China (South) and Sri Lanka.
This species has world wide distribution but more prominent in tropical and subtropical parts.

**Euborellia compressa** (Borelli)
(Figs. 70–74)

General colour brownish yellow to reddish brown; legs clear yellow; often sides of abdomen with traces of black.

Male : Head slightly longer than broad, smooth, frons weakly convex, sutures almost obsolete, hind margin feebly emarginate in middle. Eyes prominent, distinctly shorter than post-ocular length. Antennae 15–segmented or more; 1st stout, narrowed basally, slightly shorter than the distance between antennal bases; 2nd short; 3rd long and cylindrical; 4th slightly longer than broad, stout, strongly narrowed basally and shorter than preceding; 5th stouter, but shorter than 3rd; remaining gradually increasing in length distally excepting one or two apical ones, each narrowed at base. Pronotum quadrate, slightly longer than broad, anteriorly as broad as head, gently widened posteriorly, lateral margin straight, gently reflexed, hind angles rounded and margin sub-truncate; prozona weakly raised, poorly differentiated from flat metazona, median sulcus distinct. Meso- and metanotum transverse, smooth, former with hind margin truncate and latter broadly emarginate posteriorly. Sternal plates and legs typical for the genus. Abdomen may be elliptical or slender, tergites smooth above, weakly convex, sides of abdominal segments 6th to 9th rugosely striate, acute angled posteriorly with an oblique carina. Penultimate sternite transverse, narrowed posteriorly with hind margin in middle subtruncate; manubrium longer than the sternite, apically broad. Ultimate tergite transverse, almost smooth, sloping backwards, sides straight, hind margin in middle almost straight, above the bases of forceps oblique and lightly concave. Forceps with branches remote and stout near base, trigonal above in basal one third, afterwards, depressed, almost straight in basal half to two third, tapering, incurved, weakly asymmetrical, apices gently hooked, inner margin finely serrated. Genitalia with parameres about as long as broad, square shaped, external apical angle sharp, tip obtuse, oblique median membrane distinct; distal lobes with denticulated chitinous pads; virga not discernible.
Figs. 70-74: *Euborellia compressa* (Borelli), Male; 70. Anterior portion of body except ultimate tergite and forceps; 71. Posterior half of penultimate sternite; 72. Ultimate tergite and forceps; 73. Genitalia; 74. Paramere enlarged.

Female: Agrees with males in most characters except sides of abdominal segments smooth, hind angle obtuse; penultimate sternite obtuse angled in middle posteriorly and forceps with branches simple and straight.

*Types*: 3 Males, 4 Females from Uganda: Bimbia and 2 Males, 1 Female from Ibanda, may be treated as *Syntypes*, deposited in MIZT.

*Distribution*: India: Tamil Nadu (Coimbatore); Himachal Pradesh (Bilaspur and Kangra dists.); W.B. (Purulia, Midnapur and Bankura dists.).
Also recorded from Pakistan: NW Province; Chitral.

This species is extensively distributed in various countries of Africa, namely, Uganda and Zire.

In MZM collections it is represented from following localities hitherto not reported:

India: Tamil Nadu, Coimbatore, 1 Male, 200 ft.; Yercaud, Shevroy Hills, 1 Male, 1 Female, 4500 ft.; Karaikal Territory, Kurumbagaram, 1 Male—all determined by G. K. Srivastava.

Remarks: The legs are generally uniform yellow but occasionally ill defined dark band is discernible.

It can be easily separated from closely related species of the genus by pale legs and male parameres in being rectangular.

**Euborellia plebeja** (Dohrn)
(Figs. 75–80)

Figs. 75-80: *Euborellia plebeja* (Dohrn), Male; 75. Ultimate tergite and forceps; 76. Sides of abdominal segments and forceps; 77. Hind portion of penultimate sternite; 78. Genitalia; Holotype Female; 79. Anterior portion of body showing head, pronotum and a portion of elytra; 80. Ultimate tergite and forceps.

General colour blackish brown to reddish; sides of pronotum, legs and one or two ante-apical segments yellowish.

**Male:** Head slightly longer than broad, frons and occiput convex, sutures distinct, hind margin emarginate in middle. Eyes shorter than post-ocular area. Antennae 16-segmented or more, basal segment slightly shorter than the distance between antennal bases; 2nd about as, long as broad; 3rd long and slender; 4th shorter than preceding, gently expanded apically; 5th slightly shorter than 3rd, but stouter and remaining gradually increasing in length distally. Pronotum slightly longer than broad, sides slightly reflexed, gently widened posteriorly with hind margin rounded, median sulcus faint. Elytra and wings well developed. Legs typical of the genus. Abdomen convex,
punctulate, gently enlarged in middle, sides of segments acute angled and ecarinate. Penultimate sternite, gently narrowed posteriorly with hind margin straight and hardly emarginate in middle. Ultimate tergite transverse, gently narrowed backwards, hind margin faintly emarginate in middle and laterally above the base of forceps emarginate and oblique. Forceps contiguous or subremote, tapering posteriorly, almost straight with tips gently hooked and pointed, trigonal above in basal one third and weakly depressed afterwards, internal margin finely serrated. Genitalia with parameres about as broad as long, inner margin convex with a concavity at internal apical angle and external apical angle prominent; distal lobes apically with chitinous denticulated pads and virga not visible.

Female: Agrees with male in most characters but differs in having penultimate sternite obtuse in middle posteriorly; ultimate tergite comparatively more narrowed posteriorly and forceps simple and straight.

**Types**: Holotype Female deposited in IZAP.

**Distribution**: India: Meghalaya (East Khasi Hills dist.); Arunachal Pradesh (Subansiri Dist.); Madhya Pradesh (Jabalpur); Tamil Nadu (Coimbatore).

Also reported from Bhutan and China (South).

Widely distributed in the Oriental Region; perhaps with world wide distribution.

It is represented in the collection of MZM by the following specimens hitherto not reported:

India: Madhya Pradesh: Jabalpur, 5 Males, 3 Females, 1600 ft; Tamil Nadu: Coimbatore, 3 Males, 18 Females—all determined by G. K. Srivastava.

**Remarks**: Holotype Female was examined. General colour is brownish black and the four basal antennal segments of the right side are remaining. The basal antennal segment is yellowish brown and rest are blackish brown and legs are yellow. Elytra and wings are brown, latter with a narrow yellow stripe along the internal margin.

This species comes close to *E. femoralis* (Dohrn) in having well developed elytra and wings but differs, in Males, by the ecarinate sides of abdominal segments and parameres somewhat rectangular with external apical angle prominent (*vs* external angle convex in *E. femoralis*).

Steinmann (1989a) has placed *Anisolabis pallipes* Shiraki, 1905, from formosa and *Euborellia kiangsuensis* Hincks, 1937 from China as synonyms of this species.

Former was described on a female which possesses abbreviated elytra as oval lateral flaps on mesonotum and has been treated as synonym of *Euborellia annulata*
(Fabricius) in the present work. And the latter, besides being apterous, is quite distinct on the basis of male parameres, does not appear to be conspecific.

*Euborellia femoralis* (Dohrn)
(Figs. 81–86)

General colour brownish black; antennae blackish brown with one or two anteapical segments yellowish white; pronotum yellow laterally and wings with moderately broad, yellow transverse band at base; legs yellow but femora banded with black.

**Male**: Head about as long as broad, frons convex, sutures faint, hind margin feebly emarginate in middle. Eyes prominent or less so, shorter than post-ocular area. Antennae 16–segmented, 1st stout, gently expanded apically, slightly shorter than the distance between antennal bases; 2nd about as broad as long; 3rd long and slender, a little over twice longer than broad; 4th slightly shorter than preceding,
Euborellia femoralis (Dohrn), Male; 81. Dorsal view; 82. Posterior half of penultimate sternite; 83. Genitalia; Holotype Female; 84. Anterior portion of body; 85. A few basal antennal segments; 86. Ultimate tergite and forceps.

stout and gently expanded apically; 5th slightly shorter than 3rd and longer than 4th; 6th about as long as 3rd but strongly narrowed at base; remaining gradually thinning and increasing in length distally. Pronotum longer than broad, lateral margin straight, gently reflexed, widened posteriorly with hind angles and margin rounded, median sulcus distinct; prozona and metazona poorly differentiated. Elytra and wings well developed, coriaceous and smooth. Legs typical of the genus; hind tarsi with 1st segment slightly longer than 3rd. Abdomen elliptical, tergites weakly convex, finely punctulate, sides of segments 7th to 9th acute angled posteriorly, carinate and rugosely punctate. Penultimate sternite narrowed posteriorly with posterior margin subtruncate. Ultimate tergite transverse, punctulate, weakly convex above, sides straight, slightly narrowed posteriorly, weakly tumid above the root of forceps, hind margin in middle
scarcely emarginate, laterally oblique and concave. Forceps with branches subcontiguous and stout at base, gradually tapering apically, almost straight in basal two thirds, slightly incurved afterwards, often right branch more strongly incurved, apices gently hooked, inner margin finely crenulate, trigonal in basal half above, afterwards, depressed. Genitalia with parameres about as long as broad, roughly sigmoid, distal lobes apically with denticulated chitinous pads.

Female: Agrees with males in most characters except that sides of abdominal segments convex; penultimate sternite obtuse in middle posteriorly; ultimate tergite weakly transverse, more narrowed posteriorly and forceps with branches contiguous, simple and straight.

**Measurements**: (in mm)

**Types**: Type Female deposited in IZAP.

**Distribution**: India: Arunachal Pradesh, Rotung, 427m (ZSI); Orissa, Jaypore, 541m; Madhya Pradesh, Jabalpur, 1600 ft. (MZM); Tamil Nadu, Coimbatore and Anamalai Hills; Pondicherry and Karaikal (ZSI).

Also recorded from Sri Lanka, Myanmar, China, Malaya, Java, Sumatra and Sumba.

**Remarks**: Recently Bey-Bienko (1959) has reported apterous form from China and discussed various characters for its discrimination from *E. plebeja* (Dohrn).

*Anisolabis minuta* Caudell, 1907, has been synonymised by Steinmman (1989a) which is not correct. According to the original description (Caudell, 1907)" .......... by the presence of small, elongated and widely separated elytra which almost or quite immovably attached to the thorax ......", it should by a synonym of *E. annulata* (Fabricius) (= *E. stali* (Dohrn)).

Type Female (which may be considered as the Holotype) was examined and it possesses antennal segments blackish brown with one or two ante-apical segments yellowish white; pronotum yellow laterally; legs yellow, femora with a broad black band; wings with a moderately broad transverse, yellow band at base and inner wing tip with a yellow spot.

**Euborellia annandalei** (Burr)  
(Figs. 87–92)

Figs. 87-92: *Euborellia annandalei* (Burr), Male; 87. Dorsal view; 88. Sides of abdominal segments and forceps; 89. Posterior half of penultimate sternite; 90. Genitalia; 91. Paramere, enlarged; Female; 92. Ultimate tergite and forceps.

General colour yellowish brown to blackish brown; head yellowish brown; antennae with three basal segments yellow, remaining black; pronotum yellow on sides and posteriorly; legs yellow, femora in middle, banded with black and tibiae black at base and abdomen and forceps black. Build moderately stout.
Male: Head about as long as broad, convex, smooth, shining, sutures distinct, hind margin in middle slightly emarginate, Eyes black, about half as long as the postocular area. Antennae 16–17 segmented; 1st stout, expanded apically slightly shorter than the distance between antennal bases; 2nd short, about as long as broad; 3rd long and slender, a little over twice as long as broad; 4th slightly shorter than 3rd, stouter, gently expanded apically; 5th slightly longer than 4th but shorter than 3rd, gently expanded apically; 6th about as long as 3rd, remaining gradually thinning, each gently narrowed at base. Pronotum about as long as broad; anteriorly about as broad as head, lateral margin straight, reflexed, gently widened posteriorly with margin rounded, median sulcus distinct; prozona tumid and metazona weakly convex. Elytra present as narrow, ovate, lateral flaps on mesonotum, external margin straight, internal margin convex and hind margin oblique. Wings wanting. Metanotum transverse, smooth, hind margin broadly emarginate. Legs typical of the genus, hind tarsi with basal segment slightly longer than apical segment, clad with fine pubescence and double row of thick setae on underside. Abdomen elliptical, tergites convex, punctulate, sides of segments 5th to 9th gently incurved, rugosely punctate and acute angled posteriorly with a distinct carina from 6th to 9th segments only. Penultimate sternite transverse, narrowed posteriorly with hind margin in middle faintly emarginate. Ultimate tergite transverse, punctulate, gently narrowed posteriorly, laterally above with a weak fold, sides straight, hind margin in middle rough, truncate or lightly concave, laterally oblique and emarginate, median sulcus marked by a depression, disc convex, weakly sloping posteriorly. Forceps with branches stout and subcontiguous in basal one thirds, afterwards tapering and incurved, right branch often more strongly incurved, apices gently hooked with tips pointed and crossing, trigonal in basal one third, afterwards depressed, internal margin crenulate in basal one third, smooth afterwards. Genitalia with parameres flat, square, external apical angle sharp, oblique membranous fold narrow; distal lobes with chitinous denticulated pads and virga distinct.

Female: Agrees with males in most characters except that the sides of abdominal segments convex; ultimate tergite weakly narrowed posteriorly; penultimate sternite obtuse posteriorly in middle and forceps simples and straight.

*Types*: In the original description (Burr, 1906) only 3 Males are mentioned which may be considered as *Syntypes* and stated to be present in Indian Museum (Burr, 1910).

The collections of the Indian Museum, Calcutta are now preserved in the Zoological Survey of India, Calcutta. In its Collection 2 Males from India: Purneah dist. (now in Bihar (C. Paiva—no further data), perhaps represent the Burr's *Syntypes*. The fate
of third Male is not known—perhaps it may be in the BMNH since a part of Indian Museum Collections is at present available there.

Distribution: India: West Bengal (Darjeeling dist.); Bihar (Purneah dist.) and Assam (Misamari, Sonai Rupai Forest, 104m, 1 Male)—all in Z.S.I., Coll.

Record from Sri Lanka (Burr, 1910) is doubtful.

Remarks: This species comes close to *Euborellia annulata* (Fabricius) and *Euborellia abbreviata* Srivastava from India but differs from both in general colouration especially of head, basal antennal segments and pronotum; stouter build and shape of male parameres being rectangular in shape.

**Euborellia annulata** (Fabricius)
(Figs. 93–97)

Anisolabis pallipes Shiraki, 1905, *Trans Sapporo nat. Hist.*, 1 (1) : 93, fig. 3 (Female; Formosa);

**Figs. 93-97:** *Euborellia annulata* (Fabricius), Male; 93. Dorsal view; 94. Sides of abdominal segments and a portion of forceps; 95. Hind portion of penultimate sternite; 96. Genitalia; Female; 97. Ultimate tergite and forceps.

General colour black to brownish black; antennae with one or two ante-apical segments yellow but their position variable, sometimes basal segment also yellow; pronotum yellow on sides; legs yellow but femora banded with black in middle. Build slender.

Male: Head smooth, shining, about as long as broad or longer, frons convex, sutures fine but distinct, hind margin emarginate in middle. Eyes slightly less than
half the length of post-ocular area. Antennae 16-segmented; basal segment stout, narrowed basally, shorter than the distance between antennal bases; 2nd short, about as long as broad; 3rd long, slender, 2½ times longer than broad; 4th & 5th sub-equal, both slightly stouter and shorter than preceding; 6th about as long as the 3rd but stouter, gently expanded apically; remaining gradually thinning and increasing in length distally except a few apical ones. Pronotum about as long as broad, gently widened posteriorly, anteriorly as wide as head, lateral margin straight, gently reflexed, hind margin briefly rounded, median sulcus distinct; prozona raised, metazona weakly depressed. Mesonotum transverse, hind margin straight. Metanotum transverse with hind margin broadly emarginate. Elytra abbreviated in the form of a narrow, ovate lateral flap, about as long as the mesonotum, external and apical margins straight, internal margin lightly convex, smooth, coriaceous. Wings absent. Legs typical of the genus. Abdomen elliptical or gradually dilating upto 9th tergite, convex, closely punctured, sides of segments 6th to 9th acute angled posteriorly, rugose and carinated. Penultimate sternite narrowed posteriorly with margin rounded; manubrium 2½ times longer than the sternite, apically with a broad loop. Ultimate tergite transverse, disc convex, with vertical punctulated and smooth stripes alternating, laterally above convex, median sulcus marked by a longitudinal depression, hind margin in middle straight or lightly concave, oblique laterally and emarginate. Forceps with branches sub-contiguous and stout at base, gradually tapering apically, almost straight in basal two thirds, incurved in apical one third with right branch more strongly incurved, tips gently hooked and crossing, trigonal above in basal one third, inner margin finely serrated. Genitalia with parameres about as long as broad, external apical angle rounded, with inner apical concavity; distal lobes with denticulated chitinous pads apically.

Female : Agrees with males in most characters except ultimate tergite weakly transverse, slightly narrowed posteriorly; penultimate sternite obtuse posteriorly in middle and forceps simple and straight.

*Types* : Type Male of *Forficula annulata* Fabricius, 1793, deposited in UZMC (According to Brindle (1981) only one male specimen is remaining out of three specimens recorded by Zimsen (1964)).

Type Female of *Forcinella stali* Dohrn, 1864 deposited in NRSS.

Type Female of *Anisolabis pallipes* Shiraki, 1906 stated to be in the collection of Dr. S. Matsumura.

Types one Male one Female of *Anisolabis minuta* Caudell, 1907 deposited in USNM.
**Distribution**: India: Kerala: Malabar; Tamil Nadu: Nilgiri Hills, Coimbatore, Tanjore dist., Yercaud Dist., Shevroy; Karnataka: Mysore; Maharashtra: Bombay; Orissa: Mayurbhanj Dist.: Baripoda, Pottangai, 3345 ft.; West Bengal: Midnapur Dist., Contai, Calcutta & environs; Manipur: Churachandpur, 300 ft.; Lakshdwip Isls.

Also reported from Sri Lanka; Pakistan and China and other parts of Oriental Region.

Almost world wide in distribution, especially in warmer parts.

This species is represented by following collections in MZM, not hitherto reported:

"India: Tamil Nadu: Nilgiri Hills, Kallar, 1250 ft., 1 Male; Coimbatore, 7 Males, 28 Females, 11 Nymphs; Tanjore dist., Nadngadu, 2 males, 4 Females; Yercaud Shevroy Hills, 1 Female; Kerala: Malabar, Walayar Forests, 1000 ft., 1 Male, 1 Female, 3 nymphs, 1500 ft., 1 nymph—all determined by Dr. G. K. Srivastava."

Remarks: It is now established that *E. annulata* (Fabricius) (= *E. stali* (Dohrn, 1864) possesses elytra in the form of narrow ovate lateral flaps on mesonotum. Much of the confusion between *E. stali* and *E. plebeja* (Dohrn, 1863) is as a result of proposed synonym of former with the latter by Hebard (1927).

Accordingly *Anisolabis pallipes* Shiraki, 1905 from Formosa and *Anisolabis minuta* Caudell, 1907 from Porto Rico are placed as synonyms.

Besides *Mongolabis aberrans* Borelli, 1932 from Borneo which was synonymised by Steinmann (1989a) under *E. stali*, appear to be quite distinct on the basis of original description.

**Euborellia abbreviata** Srivastava
(Figs. 98–100)

General colour blackish, head yellowish brown with shades of black; pronotum yellowish laterally; legs yellowish brown and femora banded with black in middle; abdominal tergites black, hind margin of each tergite reddish.

**Male**: Head triangular, slightly longer than broad, frons raised, sutures faint, hind margin slightly emarginate in middle. Eyes small, black. Antennae partly broken, only six segments on each side remaining, 1st long, stout; 2nd small; 3rd long, slender, equal to 4th and 5th together; 6th longer than 5th. Pronotum about as long as broad, anterior and lateral margins straight, latter gently reflexed, very slightly expanded.
posteriorly with margin rounded, median sulcus faint, prozona raised, a little differentiated from flat metazona. Legs typical of the genus. Elytra abbreviated in the form of a narrow ovate lateral flap on mesonotum. Wings absent. Abdomen gently widened in middle, faintly punctulate above, sides of segments 6th to 9th rugosely punctate, acute posteriorly, a median longitudinal carina present on the sides of segments 6th to 9th only. Penultimate sternite punctate, punctuation sparse in apical half only, hind margin subtruncate in middle. Ultimate tergite twice as broad as long, very slightly narrowed posteriorly, median sulcus faint, finely punctulate, hind margin straight in middle, laterally oblique and concave. Forceps with branches remote at base, trigonal above in basal one third, afterwards depressed, tapering apically, left branch almost straight, gently curved in apical one third, right branch more strongly curved and crossing over the left, tip pointed, inner margin finely crenulate, branches flat below. Genitalia with parameres square, external apical angle convex, apex obtuse, inner margin convex, oblique membrane narrow; distal lobes with denticulated chitinous pads and a fine virga.

Female : Unknown.

SRIVASTAVA: Dermaptera

Type: Holotype Male in Z.S.I.

Distribution: India, Arunachal Pradesh.

Remarks: This species comes close to E. annulata (Fabricius) and E. annandalei (Burr) in having elytra as narrow, ovate, lateral flaps on mesonotum and sides of abdominal segment 6th to 9th carinate. It differs from the former in being slightly larger in size, i.e., 12.8mm (vs smaller size, i.e., 8.0–11.0mm in E. annulata) and male genitalia with parameres lacking inner apical concavity (vs a broad inner concavity present) and from the latter by slightly smaller size, i.e., 12.8mm (vs larger size, i.e., 13.0–16.6mm in E. annandalei); sides of abdominal segments 6th to 9th posteriorly not incurved (vs incurved) and male genitalia with external apical angle rounded (vs external apical angle sharp and projecting).

Euborellia manipurensis Srivastava
(Figs. 101–106)

General colour blackish brown; mouth parts and a few basal as well as ante-apical antennal segments yellowish brown; legs yellow and forceps reddish brown.

Male: Head slightly longer than broad, convex, sutures obliterated, slightly emerginate in middle posteriorly. Eyes triangular, about half as long as the post ocular area. Antennae (apically) broken, only 13 segments remaining, 1st long, stout, narrowed at base; 2nd small; 3rd long, cylindrical; 4th and 5th subconical and almost equal in length but both shorter than 3rd, remaining narrow at base and gently expanded at apex and gradually increasing in length distally. Sternal plates typical of the genus. Pronotum quadrate, slightly longer than broad, all margins straight, sides gently reflexed, very slightly widened posteriorly, median suture faint, prozona slightly raised and metazona depressed. Elytra abbreviated in the form of narrow, ovate flaps on the sides of the mesonotum. Abdomen long, slender, slightly enlarged in middle, punctulate, sides of abdominal segments 6th to 9th obtuse angled posteriorly, punctate and devoid of any longitudinal carina. Penultimate sternite with hind margin rounded posteriorly. Ultimate tergite transverse, sides convex and with an oblique convexity, gently contracted posteriorly, hind margin gently sinuate in middle, median sulcus distinct, above the bases of forceps punctate with oblique striations. Forceps almost straight, trigonal in basal half only, afterwards depressed, tapering apically, tip pointed and hooked, right branch near the apex slightly more incurved, inner margin crenulate. Genitalia with parameres about as long as broad, apical margin lightly convex, external apical angle rounded, oblique membrane narrow; distal lobes with chitinous denticulated pads; fissure of proparamere deeps and wide.

Female: Agrees with male in most characters except that penultimate sternite obtusely produced in middle posteriorly; ultimate tergite more strongly narrowed posteriorly and forceps with branches contiguous, simple and straight.

**Types**: Holotype Male in Z.S.I.

**Distribution**: India: Manipur: Ukhrul, 6200 ft.

**Remarks**: Due to the presence of elytra as narrow ovate flaps on mesonotum, the described species comes close to *E. annandalei* Burr and *E. annulata* (Fabricius) but differs from both in having the sides of abdominal segments ecarinate and obtuse posteriorly and by the shape of parameres lacking inner apical concavity and apical margin lightly convex.

The description of female is based on on 1 male, 3 females and 5 nymphs, 10.ix.1775 (*M.S. Shishodia coll.*) from Manipur: New churachandrapur, det. by Dr. G. K. Srivastava, preserved in the Zoological Survey of India, Calcutta.

**Uncertain species**:  
*Euborellia kumaonensis* Gangola  
(Figs. 107–110)

**Male**: Stature small, deep chestnut brown in colour, pronotum lighter laterally; apical joints of antennae, palpi and tarsi, 10th abdominal segment and lower ¾th of body covered with hairs.

Head long, shining, almost black, sutures not distinct, eyes short, post-ocular rounded; antennae 16–segmented; segment 1 and 3 quite long, rest progressively more slender. Pronotum shining, longer than broad, narrower than head, anterior margin straight, sides depressed, posterior end broad with angles round; prozona elevated, metazona flat, median suture obsolete. Elytra granulated bearing tiny hairs, less broad, carina short: Wings short with metallic lustre. Legs pale yellow, broad dark brown bands on the segments. Sternal plates having mesosternum with two black spots laterally, apex not much rounded, longer than pro- and mestasternum. Abdomen granulated, with long dense stiff hair, less depressed, sides not parallel, segments shortening up to 9th segment. Ultimate tergite quadrate, much elevated in middle with a median depression, sides not parallel, tubercles above the base of the forceps. Penultimate sternite short. Pygidium triangular. Forceps depressed, straight, black at base, tips flat and chestnut brown in colour, triangular basally, left arm shorter than right, deeply crenulated; a single tooth at the base of each branch.

**Female**: Unknown.

Types: Holotype Male stated to be deposited at DTDSN.

Distribution: India: U.P., Nainital Dist., Sher-ka-Danda Hills, 2057m.

Remarks: The above description of the species is after Gangola (1968). Since the male genitalia has not been described, it is difficult to ascertain the taxonomic status of the species.

However, on the basis of description and figures given by the author, Holotype appears to be a female of *Nala lividipes* (Dufour). The shape of pronotum; granulated elytra and abdomen and former with a short keel suggest the same.

*Euborellia askotensis* Gangola

Male: Size medium, general colour blackish-brown, slightly depressed. Head, tumid, eyes prominent, frons elevated. Antennae brown, 10–segmented, 3rd segment longer than 4th and 5th united, 4th almost equal to 2nd, rest globular. Pronotum truncate, anterior angles produced; longer than broad, sides straight and translucent; rounded posteriorly; prozona and metazona separated by a transverse groove, former with single oval spot in middle and latter with a pair of yellow spots on anterior margin. Tegmina twice as long as pronotum, ample, black along suture, vestigial keel on the costal margin, finely punctate. Legs slender, femora and tibiae banded with brown. Abdomen dark brown shaded with black, parallel sided, broad caudad. Ultimate tergite ample, smooth, quadrate, small tubercles over the roots of forceps. Forceps brown, strong, remote at base, triangular basally, curved laterad, with one tooth placed three-fifths from base.

Genital armature: Parameres clubbed at apex, tips acuminate; midrib prominent; basal vesicles facing dorsally. Preputial sac thin and membranous. Virga of the reflected penis lobe smaller than the other. Parameres tubular.

Female: Unknown.

Measurements: Not provided with the original description.

Types: Holotype Male stated to be deposited at DTDSN.

Distribution: India: Uttaranchal: Askote (Pilhoragarh Dist.). Known only from the type locality.

The shape of parameres suggests it may not be a member of *Euborellia* Burr. Perhaps it may belong to *Labidura* Leach. However, the correct position of the species could be decided only after the examination of the Holotype.

The author personally along with the concerned staff at the Department of Zoology, Thakur Dan Singh Bhist Government College, Nainital (U.P.), could not trace there the types of *E. kumaonensis* and *E. askotensis*.

**Mongolabis** Zacher

Anisolabis (Mongolabis); Bey-Bienko, 1936, *Faune de L'URSS* Dermaptera: 92 and 218.

Size small to large (10–30mm); build generally stout, occasionally slender. General colour black to blackish brown. Generally apterous, sometimes abbreviated elytra present, narrowed at base, exposing transverse scutellum and posteriorly lobed, meeting along the median line.

Male parameres about one and half times longer than broad, broadened in middle, narrowed apically forming a sort of snout, somewhat square with inner margin oblique, external apical angle generally projecting or spiniform; distal lobes with chitinous denticulated pads and accessory chitinous plates present or absent; virga may or may not be discernible.
Type species: Gonolabis woodwardi Burr, 1906 (Designated by Burr, 1911, Genera Insect., 122 : 34).

Distribution: Oriental, Ethiopian and Australian Regions.

Remarks: Srivastava, (1999) has resurrected this genus since it has line priority over Gelotolabis Zacher (Zacher, 1911).

This genus is mainly characterised on the basis of male parameres. Only this part of genitalia is useful in discriminating it from related genera and all other characters seem to be of little value.

At present only a single species of the genus is represented in India.

Mongolabis vallakadaiensis (Ramamurthi & David)  
(Figs. 111–115)

Male: General colour reddish brown to dark brownish black; legs lighter in colour.

Head longer than broad, weakly convex, surface rugose, punctate in posterior half, sutures fine, hind margin lightly emarginate in middle. Eyes about 1/3 as long as the post-ocular area. Antennae (apical segments generally broken) 10–segmented (in the material examined) with 1st segment long, stout, narrowed at base, slightly shorter than the distance between antennal bases; 2nd transverse; 3rd long and slender; 4th about as long as broad, gently expanded apically; 5th longer than 4th but a trifle shorter than 3rd; remaining segments gradually increasing in length. Pronotum longer than broad, finely punctate, sides gently diverging posteriorly with hind margin and angles rounded, median sulcus distinct in anterior half only, prozona and metazona not well differentiated. Meso- and metanotum punctate, former with abbreviated elytra, narrowed at base, exposing a transverse scutellum and posteriorly lobed, overlapping along the middle line. Abdomen convex, parallel sided, only gently widened posteriorly but afterwards narrowed from 8th tergites onwards, each tergite close to lateral margin with three smooth oval patches, roughly arranged in a triangular fashion, sides of segments convex posteriorly and ecarinate. Penultimate sternite transverse, in posterior half narrowed with hind margin convex in middle; Ultimate
Mongolabis vallakadaiensis (Ramamurthi and David); 111. Anterior portion of body; 112. Sides of abdominal segments; 113. Posterior half of penultimate sternite; 114. Ultimate tergite and forceps; 115. Genitalia (all figs. except genitalia are from the Holotype Male).

Female: Agrees with males in most characters except that ultimate tergite more narrowed posteriorly; forceps almost symmetrical and subcontiguous, inner margin with a minute tooth at basal 1/3.

Type species: Holotype Male in the Authors collection.

Distribution: India: Tamil Nadu, Shevroy Hills.

Genus: Anisolabella Zacher

Male genitalia with parameres about one and half times longer than broad, somewhat oval or squarish, broadened in middle, narrowed apically but not forming a snout (projecting), tip may be pointed or obtuse, external margin forming a sort of arch or semicircular; distal lobes Anisolabid type, virga absent or discernible, with or without denticulated pads; proparmeres divided apically into two halves, extent of incision variable.

Females similar to male in external characters except that ultimate tergite weakly transverse and forceps generally simple and straight.

Type-species: Anisolabella braueri Zacher, 1911.

Distribution: World wide but more dominant in tropical and subtropical parts.
SRIVASTAVA: Dermaptera

Remarks: Srivastava (1999) has redefined this genus and altogether 37 species are included under it.

At present only six species are represented from the Indian subcontinent.

The distribution of Indian species appears to be interesting. Excepting *A. dohrni* (Kirby) which is distributed in Sri Lanka and almost throughout India, all others have restricted distribution. *A. greeni* (Burr) is endemic to Sri Lanka and *A. nandii* (Srivastava) is confined to Peninsular India. The other three species *viz.*, *A. carinatus* (Srivastava) and *A. denticlatus* (Srivastava) alongwith *A. montshadskii* (Bey-Bienko) are found in N.E. India excepting last one which was originally described from South China.

Key to the species (based on males only)

1(8). Penultimate sternite entire posteriorly

2(3). Elytra perfect; wings generally absent ..................... *A. dohrni* (Kirby)

3(2). Elytra abbreviated or apterous

4(7). Elytra abbreviated; sides of abdominal segments ecarinate

5(6). Pronotum longer than broad, almost of uniform width throughout; elytra abbreviated, narrowed at base exposing transverse mesonotum and posteriorly lobed, inner margin slightly overlapping; sides of abdominal segments 6–9 obtuse angled posteriorly and punctate ......................... *A. greeni* (Burr).

6(5). Pronotum broader than long, widened posteriorly; elytra abbreviated as narrow, ovate, lateral flaps on mesonotum; sides of abdominal segments 7 to 9 acute angled posteriorly and rugosely punctate .......... *A. nandii* (Srivastava)

7(4). Apterous; sides of abdominal segments 7 to 8 with a median oblique carina .......................................................... *A. carinatus* (Srivastava)

8(1). Penultimate sternite emarginate in middle posteriorly

9(10). Body punctation distinct; legs with femora in distal 1/4 yellowish; sides of ultimate tergite with a distinct oblique carina and genitalia with distal lobes unarmed ......................... *A. montshadskii* (Bey-Bienko)

10(9). Body punctation feeble; legs unicolorous; sides of ultimate tergite with a week oblique fold; genitalia with distal lobes with denticulated pads .................. .......................................................... *A. denticulatus* (Srivastava)

Anisolabella dohrni (Kirby)
(Figs. 116–120)

Figs. 116-120: Anisolabella dohrni (Kirby); Male; 116. Dorsal view; 117. Posterior half of penultimate sternite; 118. Ultimate tergite and forceps; 119. Genitalia; Female; 120. Ultimate tergite and forceps.

Nannopygia dohrni Kirby, 1891, *J. Linn. Soc. (Zool.)*, 23: 508 (Female; Ceylon); Bormans, 1900, *Das Tierreich*, 11: 11.

Carcinophora caeruleipennis (pars) Bormans, 1900, *Das Tierreich*, 11: 40 (new name for Labidura femoralis Dubrony, 1879; Junior secondary homonym of Labidura femoralis Dohrn, 1863–Ceylon specimens only); Burr, 1911, *Genera Insect.*, 122: 31 (proposed as a synonym of Nannopygia dohrni Kirby, 1891).

Anisolabis brunneri?; Burr (néc Dohrn), 1906, *J. Asiat Soc. Beng* (N.S.), 2: 389 (Female (néc Male), Purneah, Dist., N. Bengal (now in Bihar).

Psalis lefroyi Burr, 1910, *Fauna British India, Dermaptera* : 77, pl. 3, fig. 20 (Female (not Male), Bombay, Mahim, "feeding on plaintain roots", Pusa Bengal).

Male: General colour blackish to reddish brown, antennal segments 2nd, 13th and 14th and pronotum laterally yellow; legs yellow but femora banded with black.

Head smooth, about as long as broad, triangular, frons convex, sutures faint. Eyes black, shorter than post-ocular area. Antennae 17–segmented, 1st shorter than the distance between antennal bases; 2nd short; 3rd long and slender; 4th and 5th almost equal in length. Pronotum slightly longer than broad, anterior margin straight, sides very slightly concave in middle, hind margin briefly rounded, median sulcus faint, prozona feebly convex. Elytra perfect, smooth, meeting along the middle line, sometimes at base axillary angles slightly rounded off to show a small scutellum, hind margin truncate, occasionally slightly oblique. Legs normal. Wings wanting; rarely present. Abdomen punctate, convex, gently enlarging posteriorly, sides of segments 6 to 9 obtuse angled posteriorly, smooth or rugosely punctate. Penultimate sternite triangular with hind margin briefly rounded or sub-truncate; manubrium three times as long as the sternite with its apex dilated. Ultimate tergite transverse, gently narrowed posteriorly, laterally with a longitudinal fold, hind margin trisinuate, laterally feebly oblique, median sulcus short. Forceps with branches subcontiguous at base, trigonal
The Fauna of India and the Adjacent Countries

with ridge present in basal one third only, weakly asymmetrical, right branch more incurved and crossing over the left near apex, tip pointed, gently hooked, inner margin finely crenulate. Genitalia with parameres broadest at about middle, inner margin straight; distal lobes with denticulated chitinous pads.

Female: Agrees with males in most characters except that ultimate tergite comparatively narrowed posteriorly; penultimate sternite obtusely rounded, in middle, posteriorly and forceps with branches contiguous and straight.

**Types**: Type Female of *Psalis dohrni* Kirby, 1891 deposited in BMNH.

Syntypes 1 Female (not Male) and 1 Male nymph of *Psalis lefroyi* Burr, deposited in BMNH.

Holotype Male, Paratypes: 2 Females and 1 nymph of *Paralabis antennata* Ramamurthi and David, 1973 stated to be with the author.

**Distribution**: Sri Lanka: Western, Sabaragamuwa, Southern, Central and North Central Provinces; India: Tamil Nadu (Kallar); Andhra Pradesh (Gyotimamidi, E. Ghats); Maharashtra (Poona, Satara, Koyna Valley) and Assam (Sadiya).

**Remarks**: Generally wings are absent in this species but Srivastava (1987a) has recorded winged forms from Sri Lanka and India.

**Anisolabella greeni** (Burr)

(Figs. 121–124)

*Borellia greeni*; Burr, 1910, *Fauna British India, Dermaptera*: 87 (Male, Female; Ceylon and India: Nilgiri Hills).

Figs. 121-124: Anisolabella greeni (Burr), Male; 121. Dorsal view; 122. Sides of abdominal segments and base of forceps; 123. Penultimate sternite and basal portion of manubrium; 124. Genitalia.

Anisolabella greeni; Srivastava, 1999, Rec. zool. Surv. India, 97 (1) : 86.

Male: General colour shining dark blackish brown; antennae and legs dark brown; whole body i.e., head, pronotum, elytra, exposed part of mesonotum, metanotum and abdominal tergites finely but distinctly punctate.

Head longer than broad, convex above, hind margin emarginate in middle; antennae 14–segmented or more, 1st stout, expanded apically, longer than the combined length of 2nd to 4th; 2nd short, about as long as broad; 3rd long and slender, longer than the 4th and 5th; 6th onwards segments gradually increasing in length and each segment gently expanded apically. Eyes shorter than the post-ocular length. Pronotum slightly longer than broad, all margins straight, sides gently reflexed, median sulcus faint. Elytra abbreviated, narrowed in basal half, exposing a large transverse mesonotum, afterwards greatly enlarged and slightly overlapping along the median line, hind margin straight. Legs normal. Abdomen spindle shaped, moderately convex above, sides of segments 6 to 9 obtuse angled posteriorly, pilose, shining and punctate.
Penultimate sternite faintly punctate, triangular, hind margin in middle obtuse. Ultimate tergite transverse, gently sloping and narrowed backwards, hind margin straight in middle, laterally slightly oblique. Forceps stout, remote and broadened at base, tapering apically, almost straight in basal two thirds, afterwards gently incurved with apices hooked and crossing, trigonal above in basal one thirds, afterwards depressed, inner margin faintly serrated, with a minute tooth at about middle. Genitalia with parameters gradually narrowing from base to apex, external margin regularly convex and inner margin concave; distal lobes unarmed.

Female: Agrees with male in most characters except that pronotum sometimes gently enlarged posteriorly and about as long as broad and sides of abdominal segments convex posteriorly.

**Measurements**: (in mm)

**Types**: Type Male in BMNH; designated by Hebard (1923). This may be treated as the 'Lectotype'.

Burr's (1899) description of the species was based on 3 Males and 3 Females which are "Syntypes" and preserved in the BMNH.

**Distribution**: Sri Lanka (North-Western, Uva, Central and North-Central Provinces).

Records from South India (Burr, 1910; Burr, 1914 and Srivastava, 1970) are doubtful. Their identity could be established only after the examination of male genitalia.

**Remarks**: This species externally resembles *Gonolabis punctata* (Srivastava, 1978) from South India but differs by its distinctive male genitalia, especially parameres.

**Anislabella nandii** (Srivastava)

(Figs. 125–128)

Male: General colour shining brownish black with varying degree on certain body parts; basal and 2nd antennal segments and legs yellowish brown.

Head smooth, slightly longer than broad, globose, frons convex, sutures fine, hind margin almost straight. Eyes not prominent, about half as long as the post-ocular length. Antennae 17–segmented or more (since apical ones broken in the specimens examined), 1st segment distinctly shorter than the distance between antennal bases;
2nd about as long as broad; 3rd long and cylindrical; 4th shorter than 3rd; 5th and 3rd almost equal; remaining gradually becoming slender and narrowed basally. Pronotum smooth, slightly broader than long, widened posteriorly, lateral margins straight, gently reflexed, hind angles and margin rounded, median sulcus faint; pro- and metazona not well differentiated. Mesonotum obscurely punctate and with elytra as narrow, lateral ovate flaps, median sulcus faint, hind margin straight. Metanotum transverse, median sulcus faint, obscurely punctate, hind margin broadly concave.

Legs normal. Abdomen gradually enlarging posteriorly, convex above, punctation feeble, sides of segments obtuse angled posteriorly and feebly punctate and that of 7th to 9th acute angled posteriorly and rugosely striate. Penultimate sternite triangular, obscurely punctate, hind margin in middle almost truncate. Ultimate tergite strongly transverse, smooth, feebly convex but gently depressed in middle posteriorly, sides straight with an oblique carina, above the base of forceps with a feebly raised area, hind margin trisinuate, laterally oblique. Forceps stout, remote, dilated and trigonal at base with a drosal ridge in basal one fourth only, afterwards depressed, tapering apically, incurved in apical two thirds, apices gently hooked and pointed, inner margin

feebly dentate. Genitalia with parameres roughly semicircular, about twice as long as broad, narrowed apically with external margin regularly convex, inner margin feebly concave, distal lobes with a small denticulated pad.

Female: Agrees with males in most characters except that sides abdominal segments smooth and convex; penultimate sternite obtuse posteriorly; ultimate tergite narrowed posteriorly and forceps simple, almost straight and contiguous.

Types: Holotype Male, Paratypes: 2 Males, 2 Females and 1 nymph deposited in the ZSI.

Distribution: India: Karnataka, Dist. Kolar, Nandii Hills. Known only from the type locality.

Remarks: This species can be easily separated from the other Indian species of the genus by the presence of elytra as narrow ovate, lateral flaps on mesonotum. Besides male genitalia, especially parameres are distinctive.

**Anisolabella carinatus** (Srivastava)
(Figs. 129–132)

Male: General colour dark blackish brown, legs and antennae reddish brown, sides of abdomen, ultimate tergite and forceps with traces of black. Whole body clad with long and short golden pubescence.

Head slightly longer than broad, weakly depressed, sutures distinct, hind margin slightly emarginate in middle. Eyes shorter than the post-ocular length. Antennae 11-segmented or more (partly damaged); 1st stout, gently expanded apically and shorter than the distance between antennal bases; 2nd short; 3rd long and slender; 4th and 5th subequal, globular and both shorter than the 3rd; 6th onwards segments gradually increasing in length and each gently expanded apically. Pronotum longer than broad, anteriorly slightly narrower than the head, sides straight, parallel sided, gently reflexed,
hind margin subtruncate, median sulcus faint; prozona weakly convex and not well
differentiated from flat, weakly convex metazona. Meso-and metanotum transverse,
former with hind margin truncate and latter broadly sinuate. Elytra and wings wanting.
Legs normal, with long pubescence, hind tarsi with 1st segment slightly shorter than
the combined length of 2nd and 3rd, covered with two rows of short stiff hairs on
underside. Abdomen weakly depressed, punctate, tergites gradually enlarging
posteriorly, sides of segments 6 to 9 acute angled posteriorly but median longitudinal
carina present on segments 7th and 8th only. Penultimate sternite narrowed
posteriorly, obtuse in middle. Ultimate tergite weakly transverse, disc feebly depressed,
median sulcus distinct, sides with a distinct oblique carina, hind margin in middle
almost straight, very slightly oblique on sides, the area close to hind margin with
serrations. Forceps subcontiguous, tapering apically, left branch almost straight, only
gently incurved near apex, right branch incurved from middle and crosses over the
left a little before apex, apices gently hooked and pointed, inner margin serrated.
Genitalia with parameres broadest at base, external margin convex, inner margin
concave; distal lobes with a pair of chitinous, denticulated rods.

Female : Unknown.

(Figs. 133–138)

Anisolabis (Paralabis) montshadskii, Bey-Bienko, 1959, Ent. Obozr., 38 : 600, fig. 16 (Male, Female; China : Yunnan); Sakai, 1982, Bull. Daito Bunka Univ., 20 : 27.

Anisolabis montshadskii; Steinmann, 1975, Folia ent. hung., 28 : 154, fig. 12 3 (Paratypes); Steinmann, 1989, World Catalogue of Dermaptera : 225.

Anisolabella montshadskii; Srivastava, 1999, Rec. zool. Surv. India, 97(1) : 86.

Male : General colour dark blackish brown, mouth parts and distal half of basal antennal segments, 2nd and a few preapical ones yellow; legs with femora in distal one fourth and whole of tibia and tarsi yellowish; sides of pronotum light brown.

Head slightly longer than broad, smooth, sutures faintly marked. Eyes shorter than the post-ocular length. Antennae 15–segmented or more; 1st about as long as the distance between antennal bases, narrowed basally; 2nd small, transverse; 3rd long and cylindrical almost equal to 5th; 4th and 5th stout; 4th slightly shorter than the preceding; 6th onwards segments gradually increasing in length and gently expanded apically. Pronotum about as long as broad, gently expanded posteriorly, all margins straight, sides gently reflexed. Legs normal. Elytra and wings wanting. Abdomen weakly convex, gently expanded posteriorly, feebly punctulate, punctuations weaker in posterior half of each tergite, lateral tubercles on 3rd and 4th tergites weakly developed, sides of segments 7 to 9 more rugosely punctured, ecarinate and obtuse angled posteriorly. Penultimate sternite broadly sinuate posteriorly. Ultimate tergite transverse, narrowed posteriorly, almost smooth, median sulcus distinct, oblique carina present on sides. Forceps trigonal above in basal one fourth, afterwards depressed, tapering apically, incurved in apical one third, right branch more incurved and crossing over the left, internally crenulate. Genitalia with distal lobes lacking virga or chitinous teeth.
Figs. 133-138: *Anisolabella montshadskii* (Bey-Bienko), Male; 133. Anterior portion of body; 134. Sides of abdominal segments and forceps; 135. Hind portion of penultimate sternite; 136. Ninth and ultimate tergites and forceps; 137. Genitalia; Female; 138. Ultimate tergite and forceps.

Female: Agrees with male in most characters except that the abdomen more feebly punctulate and the sides of all the abdominal segments convex, not rugose; penultimate sternite obuse posteriorly and forceps simple and straight.

*Measurements*: (in mm)

*Types*: Bey-Bienko (1959) while describing the species has recorded 6 Males, 1 Female including 'Type' which may be considered as the Holotype male, and rest as Paratypes.
According to Steinmann (1975b, 1989a) 3 Paratypes are deposited in AZL and for Type male- repository is unknown, perhaps it may be in CASP.

**Distribution**: India: Arunachal Pradesh, Lohit dist., Tihun and Wakro, 1700 ft. and China: Yunnan.

**Remarks**: Out of the specimens from India, one male possesses forceps with branches subcontiguous and apices are almost touching.

*Anisolabella denticulatus* (Srivastava)
(Figs. 139–143)

Male: General colour reddish brown with traces of black on certain body parts; mouth parts yellowish; 1st and 2nd antennal segments and legs testaceous brown.

Head slightly longer than broad, smooth, convex above, sutures fine but distinct, gently narrowed behind eyes, hind margin almost straight, faintly depressed in middle. Eyes about half as long as the post-ocular length. Antennae (partly broken) 17–segmented or more; 1st stout, about as long as the distance between antennal bases, narrower at base and expanded apically; third onwards length of corresponding segments on right and left side variable in Holotype male only, segments more elongated in right antennae, left antennae with 3rd segment long and cylindrical; 4th shorter than the preceding, narrowed basally; 5th equal to 3rd, further segments gradually increasing in length and thinning; antennae of right side with 3rd segment cylindrical, only slightly shorter than the 1st and almost equal to 6th; 4th and 5th shorter than 3rd. Pronotum about as long as broad, smooth, sides straight, feebly reflexed in middle only, gently diverging posteriorly with hind margin sub-rotundate, median sulcus faintly marked, prozona weakly raised and poorly differentiated from flat metazona. Meso- and metanotum transverse, smooth, hind margin truncate in the former and broadly emarginate in the latter. Elytra and wings absent. Legs normal. Abdomen weakly convex, enlarging from base to 6th tergite and narrowing feebly from 7th to 9th tergites, finely punctulated, lateral tubercles on 3rd and 4th tergites almost obsolete, sides of segments 6 to 9 acute angled, rugosely punctate but punctuation weaker on 6th segment. Penultimate sternite transverse, narrowed posteriorly, hind margin broadly sinuate, in posterior half above with a rounded and depressed area and a faintly raised longitudinal stripe in the middle. Ultimate tergite transverse, almost smooth except for a few punctations sparsely placed, narrowed posteriorly, laterally raised above in middle, median sulcus distinct, laterally oblique
Figs. 139-143: *Anisolabella denticulatus* (Srivastava), Holotype Male; 139. Anterior portion of body; 140. Hind portion of penultimate sternite; 141. 8th, 9th and ultimate tergites and forceps; 142. Genitalia; Female; 143. Ultimate tergite and forceps.

carina weakly marked, hind margin trisinuate, oblique laterally. Forceps subcontiguous, branches stout, tapering apically, almost straight in basal two third, afterwards gently incurved, right branch more strongly incurved and crossing over the left, apices gently hooked with tip pointed, trigonal above in basal one third and afterwards depressed, internal margin faintly crenulate. Genitalia with parameres about twice as long as broad, gradually narrowing apically; distal lobes with chitinous denticulated pads apically.

Female: Agrees with male in most characters except that the sides of abdominal segments smooth, convex posteriorly; penultimate sternite obtusely rounded posteriorly; ultimate tergite comparatively strongly narrowed posteriorly and forceps contiguous, simple and straight.

Types: Holotype Male, Paratypes: 2 Males, 9 Females and 2 nymphs deposited in the Z.S.I.

At present known from the type localities only.

Remarks: This species was confused with Paralabis montshadskii Bey-Bienko, by Srivastava (1971 and 1972) but differs, in males, by the uniformly coloured legs, comparatively feeble body punctuations, weakly developed oblique carina on the sides of ultimate tergite and genitalia provided with chitinous denticulated pads at the apical end of distal lobes.

The general body colouration varies between reddish brown and dark blackish brown.

Genus Gonolabis Burr

SRIVASTAVA: Dermaptera

Size small to large (7.5–23.5 mm, including forceps). Apterous or with elytra abbreviated in various shapes. Antennae multisegmented; eyes shorter than the postocular area. Abdomen gradually enlarging posteriorly, attaining maximum width at ultimate tergite or spindle shaped. Forceps short arcuate or long and slender, contiguous or sub contiguous near base, gently incurved apically. Male genitalia with parameres two to two and half times longer than broad, almost of uniform width throughout, external apical angle convex, inner apical angle sometimes acute; apical margin convex, gently oblique or straight; distal lobes with chitinous plates and virga present or absent.

Types species: Anisolabis javana Bormans, 1883.

Distribution: Oriental, Australian and Ethiopian Regions.

Remarks: This genus has been redefined by Srivastava (1999) on the basis of male parameres.

Altogether nine species (including one new species) are known from Indian subcontinent. Of these Gonolabis electa Burr, is widely distributed in the Oriental Region and adventive to Ethiopian Region but not recorded so far from India. The remaining eight species are confined to Peninsular India.

Key to species (based on Males only)

1(2). Size small (6.1–11.5 mm, including forceps); apterous; abdomen gradually enlarging from base to ultimate tergite; genitalia with parameres in length a trifle less than double its width, comparatively broader ......................................................... ................................. Gonolabis electa Burr

2(1). Size medium to large (12.0–25.0 mm, including forceps); elytra abbreviated; wings wanting; genitalia with parameres a little over two to two and half times longer than broad, comparatively narrower, especially near apex

3(8). Penultimate sternite with a tuft of setae, in the middle, on the posterior margin

4(5). Posterior margin of penultimate sternite slightly emarginae in middle........

................................................................................................. G. penicillata (Borelli)

5(4). Posterior margin of penultimate sternite entire

6(7). Posterior margin of penultimate sternite in middle acute .........................

................................................................................................. G. emarginata (Ramamurthi & David)

7(6). Posterior margin of penultimate sternite in middle rounded .....................

................................................................................................. G. analis (Ramamurthi & David)
8(3). Penultimate sternite without a tuft of setae, in middle, on posterior margin

9(10). Head with a deep cavity, in middle, close to hind margin (rarely weakly developed) ................................................................................. G. sisera (Burr)

10(9). Head without a cavity

11(12). Elytra present as narrow lateral ovate flaps on mesonotum .................

..............................................................G. burri (Srivastava)

12(11). Elytra narrowed at base exposing a transverse scutellum; afterwards, in apical half, enlarged and meeting along the median line

13(16). Sides of abdominal segments obtuse angled or convex posteriorly, rugose & ecarinate; genitalia with parameres along the internal margin concave, tip blunt, not strongly narrowed; dital lobes without chitinous rods or virga

14(15). Genitalia with parameres narrowed in apical one third with tip obtuse, apical margin oblique.................................................................................G. punctata (Srivastava)

15(14). Genitalia with parameres gently broader apically, tip represented by a small point, apical margin straight, parallel to basal margin

..............................................................G. krishnappai sp. n.

16(13). Sides of abdominal segments acute angled posteriorly, with a longitudinal carina of segments 5–7 only; genitalia with parameres narrowed gradually from apical one third with tip pointed; inner margin almost straight, apical angle and margin forming an arc; distal lobes with a chitinous rod and fine virga ...................................................................... G. nilgiriensis (Srivastava)

Gonolabis electa Burr

(Figs. 144–146)

Figs. 144-146: Gonolabis electa Burr, Male; 144. Dorsal view; 145. Penultimate sternite and forceps; 146. Genitalia.

Male: General colour reddish brown to black; antennae dark brown or lighter in colour; basal segment sometimes yellow; sides of pronotum and legs yellow, femora darker.

Head broader than long, frons convex, sutures faint, hind margin scarcely emarginate in middle posteriorly. Eyes shorter than post-ocular area. Antennae 15-segmented, 1st stout gently expanded apically, shorter than the distance between antennal bases; 2nd short; 3rd long and cylindrical; 4th elongated, shorter than 3rd; 5th cylindrical almost equal to 3rd, remaining gradually thinning and increasing in length distally, each narrowed at base. Pronotum about as long as broad, quadrate, gently widened posteriorly, all margins straight, prozona gently convex and indistinctly separated from weakly depressed metazona, median sulcus faintly marked. Apterous. Mesonotum with hind margin straight and metanotum emarginate posteriorly. Legs typical of the genus, hind tarsi with 1st segment almost equal to the combined length of 2nd and 3rd. Abdomen narrowed at base, gradually increasing in width posteriorly and attaining maximum width at 9th tergite, surface above punctulated, weakly convex, sides of segments acute angled posteriorly. Penultimate sternite broadly
rounded posteriorly, scarcely emerginate in middle. Ultimate tergite approximately one and half times broader than long, almost smooth, sometimes with one or two rows of punctuations, weakly raised on either side of middle line, median sulcus distinct, laterally with a short, oblique carina, hind margin in middle almost straight, oblique above the base of forceps. Pygidium vertical. Forceps with branches remote at base, short, arcuate, trigonal above in basal one third, afterwards depressed, internally obscurely serrated. Genitalia with parameres, flat, broad, about twice as long as broad, externally rounded near apex; distal lobes with virga discernible or not visible in old specimens, chitinous pads present.

Female : Agrees with males in most characters except that ultimate tergite narrowed posteriorly; penultimate sternite less broadly rounded and convex posteriorly in middle and forceps simple and straight.

*Types* : 'Type Male' of *Gonolabis electa* Burr, 1910 in BMNH.

Burr (1910) in the original description has not mentioned the number of specimens except 'Type' in the author's collection. However, the legend to Pl. III, fig. 21 it is mentioned as 'Type Male'

Syntypes 2 Male of *Gonolabis calas* Fernando, 1961, deposited in the Department of Zoology, University of Ceylon, Colombo, Sri Lanka.

*Distribution* : Sri Lanka : Southern, Western Sabaragamuwa, Uva, North Western and Central Provinces.

A widely distributed species in the Oriental Region, recorded from Sri Lanka, Malaysia, Vietnam, Indonesia (Java, Sumatra and Lesser Sunda Isls) and Philippine Isls.

Also recorded from Africa as adventive (Brindle, 1978), Muritius (Srivastava, 1984a) and Seychelles.

*Remarks* : This species can be easily separated from other Indian species by its smaller size and comparatively broader parameres in being about twice as long as broad with external apical angle and margin broadly rounded.

*Gonolabis penicillata* (Borelli)

(Figs. 147–151)

Figs. 147-151: *Gonolabis penicillata* (Borelli), Male; 147. Dorsal view; 148. Posterior half of penultimate sternite; 149. Genitalia; 150. Paramere and a portion proparamere and distal lobe, enlarged; Female; 151. Ultimate tergite and forceps.

Male: General colour blackish to reddish brown; mouth parts, antennae with basal segments, sides of pronotum and legs yellowish or yellowish brown.

Head smooth, shining, slightly longer than broad, weakly convex, sutures faint, hind margin feebly emarginate in middle. Eyes short, about 1/3 as long as post-ocular area. Antennae 17-segmented; 1st stout, gently expanded apically, slightly shorter than the distance between antennal bases; 2nd about as long as broad; 3rd long and slender; 4th slightly shorter than the 3rd; 5th slightly shorter than 3rd but longer than 4th; 6th about as long as 3rd; remaining gradually increasing in length and thinning. Pronotum smooth, slightly longer than broad, gently widened posteriorly, sides straight, gently reflexed, hind margin lightly convex, median sulcus distinct; prozona and metazona convex and well differentiated. Elytra faintly punctulate, axillary angles rounded off to show a transverse scutellum, posteriorly lobed, inner margin along the median line slightly overlapping. Metanotum faintly punctulate, hind margin broadly concave. Legs typical of the genus, hind tarsi with 1st segment slightly longer than the combined length of 2nd and 3rd, covered with two rows of thick hairs on underside. Abdomen spindle-shaped, tergites weakly convex, faintly punctate, sides of segments rugose, from 4th to 9th acute angled posteriorly but carina present on 5th to 9th only. Penultimate sternite transverse, narrowed posteriorly, hind margin truncate, sometimes scarcely emarginate in middle, along the median line in posterior half with a convexity, furnished with a tuft of setae apically, close to hind margin. Ultimate tergite transverse, gently narrowed posteriorly, weakly convex above, median sulcus distinct, close to hind margin faintly rugose, above the base forceps weakly tumid, hind margin trisinuate, laterally above the base of forceps oblique. Pygidium vertical. Forceps with branches remote or subcontiguous, stout at base, afterwards tapering apically, left branch almost straight in basal two thirds and incurved afterwards, right branch more strongly incurved a little beyond middle and crosses over the left, apices gently hooked, trigonal above in basal one third only, internally at base with a minute tooth. Genitalia with parameres a little more than twice as long as broad, gently narrowed towards inner apical angle, membrane distinct; distal lobes with a chitinous rod.

Female: Agrees with male in most characters except that penultimate sternite obtuse posteriorly, lacking tuft of setae in middle close to hind margin; ultimate tergite more strongly narrowed posteriorly and forceps simple & straight, inner margin faintly serrated.

Types: Borelli (1911) in the original description mentions several examples, consisting of male, Female & Juvenile in (Paris Museum). Therefore all this material could treated as Syntypes.
However, Steinmann (1989a, p. 256) states "Type Male: Museo ed Istituto di Zoologia Sistematica, Torino ......."

**Distribution**: India: Tamil Nadu, Nilgiri Hills (Coonoor, ca 1800m; Ootacmund, 2330m and Dodabetta Peak, 2475).

**Remarks**: This species occurs in large numbers in various localities of India: Nilgiri Hills and shows variation in body size and general colouration.

**Gonolabis emarginata** (Ramamurthi & David)

(Figs 152–155)

Male: General colour reddish brown to black; basal antennal segment, mouth parts and legs yellow.

Head triangular, a trifle longer than broad, frons convex, sutures obsolete, hind margin in middle with a slight emargination. Eyes about half as long as the postocular area. Antennae 17–segmented, basal segment stout, expanded apically, slightly shorter than the distance between antennal bases; 2nd short, about as long as broad; 3rd long & slender; 4th a little shorter and stouter than preceding; 5th slightly longer than 4th but shorter than 3rd; 6th about as long as 3rd; 7th onwards segments gradually thinning, each narrowed at base. Pronotum slightly longer than broad, anteriorly as broad as the posterior margin of head, sides straight, gently reflexed and diverging posteriorly, hind margin subrotundate; prozona and metazona weakly convex. Elytra and metanotum same as in *G. penicillata*. Legs typical of the genus, hind tarsi with 1st segment slightly shorter than 3rd, covered on underside with two rows of thick hairs. Abdomen spindle shaped, tergites weakly convex, micro-reticulated, sides of segments acute angled posteriorly with a carina on 5th to 7th only. Pygidium not distinct, vertical. Penultimate sternite with hind margin rounded and in middle with an acute point covered with a tuft of setae. Ultimate tergite transverse, gently narrowed posteriorly, weakly convex above laterally, hind margin trisinuate, above the base of forceps oblique. Forceps stout, subcontiguous at base, gradually tapering apically, left branch almost straight in basal 2/3, afterwards incurved, right branch strongly incurved a little beyond middle, trigonal in basal 1/3, afterward depressed, apices hooked with tip sharply pointed, inner margin with a triangular tooth at basal 1/3, otherwise margin obscurely serrated. Genitalia with parameres a little over twice as long as broad, gently expanded at external apical angle, internal apical angle obtuse; membrane broader in middle; distal lobes with virga and a chitinous rod.
Female: Agrees with males in most characters except that penultimate sternite obtuse posteriorly, without median apical tuft of setae and forceps simple and straight.

**Types**: Holotype Male, Allotype Female and Paratypes 2 Females with the author.

**Distribution**: India: Tamil Nadu, Nilgiri Hills.

**Remarks**: The record of *Epilabis analis* by Srivastava (1978) on a male, is actually referable to this species.
The present description is based upon several males and females from India (Tamil Nadu, Nilgiri Hills) determined by Dr. G. K. Srivastava, preserved in Z.S.I.

Male parameres of Holotype figured by Ramamurthi & David (1973) show a slight emargination in middle of external margin which may not be structural. It may be perhaps due to shrinkage during mounting. The parameres figured in this work are slightly different but overall shape fits within the intra-specific variational range as has been observed in the case of Gonolabis sisera (Burr).

**Gonolabis analia** (Ramamurthi & David)  
(Figs. 156–162)

*Epilabis analis*; Steinmann, 1989, *Das Tierreich*, **105**: 175.

Male: General colour reddish to blackish brown; legs and antennae yellow.

Head smooth, slightly longer than broad, frons raised, occiput and genae weakly depressed, hind margin in middle feebly emarginate. Eyes shorter than post-ocular area. Antennae 16-segmented or more (generally apical segments broken); 1st stout, expanded apically, only slightly shorter than the distance between antennal bases; 2nd short, about as long as broad; 3rd long and slender; 4th & 5th equal and both equal to 3rd in length; 6th onwards gradually increasing in length and each narrowed basally. Pronotum slightly longer than broad, anteriorly about as broad as head, sides straight, gently reflexed and diverging posteriorly, hind angles rounded and margin subtruncated, median sulcus distinct; prozona and metazona weakly raised. Elytra same as in *G. penicillata*. Wings wanting. Metanotum transverse, hind margin broadly emarginate. Legs typical of the genus. Abdomen enlarged in middle, tergites weakly convex, sides of segments 5–8 rugose, acute angled posteriorly and carinate. Penultimate sternite with all margins rounded, narrowed posteriorly, a median raised area from middle to apex present with a tuft of hairs close to hind margin. Ultimate tergite transverse, gently narrowed and sloping backwards, laterally above gently raised, median sulcus short but distinct, hind margin in middle straight, laterally above base of forceps oblique and emarginate. Forceps remote or subcotiguous and stout at base, tapering apically, left branch almost straight, incurved in apical 1/3 and right branch strongly incurved in a little beyond apical 1/2, trigonal above in basal 1/3, inner margin finely serrated with a tooth at basal 1/3. Genitalia with parameres a little two times longer than broad, inner apical angle acute, external apical angle rounded or convex; membrane oblique and broader in middle; distal lobes with a distinct virga and chitinous plate.
Female: Agrees with male in most characters except that sides of abdominal segments on sides convex posteriorly and ecarinate; penultimate sternite obtuse posteriorly, lacking apical tuft of setae; ultimate tergite comparatively more narrowed and forceps simple and straight.

**Types:** Holotype Male, Allotype Female and Paratype 1 Male with the author.

**Distribution:** India: Tamil Nadu, Nilgiri Hills.

**Remarks:** The above description of the species is based upon specimens from India, Nilgiri Hills det. by Dr. G. K. Srivastava and preserved in the Zoological Survey of India.
This species is very close to *G. emarginata* (Ramamurthi and David) but differs mainly by the shape male penultimate sternite in having the hind margin rounded (*vs* hind margin rounded with a small acute point in middle in *G. emarginata*).

**Gonolabis sisera** (Burr)

(Figs. 163–169)

Male : General colour reddish to blackish brown; three basal and a few anteapical antennal segments and legs yellows, often latter orange yellow.

Head slightly longer than broad, frons convex, close to hind margin above with an oblong deep cavity, sutures faint. Eyes distinct, about 1/2 as long as the post-ocular area. Antennae 18–segmented, basal segment stout, slightly shorter than the distance between antennal bases, gently expanded apically; 2nd short, about as long as broad; 3rd long and slender; 4th subclavate, slightly shorter than the preceding; 5th subclavate, about as long as 3rd; 6th onwards segments increasing gradually in length and thinning, each narrowed at base and expanded apically. Pronotum longer than broad, gently widened posteriorly, apical lateral angle, a little projecting, lateral margin straight, hind margin and lateral angles briefly rounded, median sulcus distinct; prozona convex and metazona depressed. Elytra in shape similar to *G. penicillata*. Legs stout, tarsi long, covered with thick hairs on underside; hind tarsi with 1st segment almost equal to combined length of 2nd and 3rd. Abdomen broader in middle from 6th to 8th tergites, convex above, finely punctuate, sides of segments 6th to 9th acute angled posteriorly, rugose and carinate. Penultimate sternoite triangular, posteriorly in middle obtusely rounded. Ultimate tergite transverse, narrowed posteriorly, smooth, weakly convex, laterally above raised, median suture distinct but
Figs. 163-169: Gonolabis siser (Burr), Male; 163. Dorsal view; 164. A few basal antennal segments; 165. Hind portion of penultimate sternite; 166. Penultimate sternite and bases of forceps; 167: Ultimate tergite and forceps; 168-169. Genitalia (Figs. 164-167 from the Nomotype (Holotype) Male).

short, hind margin in middle almost straight, laterally above base of forceps oblique and lightly emarginate. Forceps subcontiguous, stout, tapering apically, left branch in apical 1/3 and right branch incurved beyond apical 1/2, crosses over left or touching, apices hooked, tips pointed, trigonal above in a little beyond basal 1/3, inner margin with a minute tooth at basal 1/3. Genitalia with parameres a little over twice as long as broad, external angle convex, tip acute or obtusely produced, membrane oblique, enlarged in middle, often covering inner margin of paramere; virga not distinct.

Female: Agrees with male in most characters except that head without a concavity; sides of abdominal segments convex; penultimate sternite obtuse in middle posteriorly and forceps simple and straight.

**Measurements**: (in mm)

*Types*: Nomotype Male (which may considered as the Holotype) preserved in IARI.
Burr's (1914) original description was based on 2 Males. Besides above Nomotype Male, perhaps the other Male (Paratype) is deposited in BMNH.

**Distribution**: India: Tamil Nadu: Anamalai Hills, 2400–4200 ft.; Nilgiri Hills (Valparai, Hills Grove, Coonoor and Udhgamandalam (néc Ootacamund) and Kerala.

**Remarks**: This species occurs in large numbers in Western Ghats (India) and is quite distinctive in having a deep cavity on the head but in one male from Kerala preserved in the Zoological Survey of India, Calcutta, it is almost obsolete and the penultimate sternite is distinctly projecting in middle posteriorly.

Male parameres show minor variation but overal shape is of Gonolabid type. Apex may be narrowed to a obtusly produced point or small point. The membrane is broader in middle, covering sometimes, the inner margin of paramere to make it appear as wavey especially, in mounts from old specimens.

**Gonolabis burri** (Srivastava)

(Figs. 170–172)

**Male**: General colour brownish black; elytra and pronotum black but latter yellow on sides; legs light brown and femora banded with black.

Head slightly longer than broad, triangular, smooth, frons convex, sutures distinct, hind margin slightly emarginate in middle. Eyes short, about 1/3 as long as postocular area. Antennae 13-segmented, 1st stout gently expanded apically, slightly shorter than the distance between antennal bases; 2nd about as long as broad; 3rd long and slender; 4th and 5th shorter than 3rd; 6th almost equal to 3rd, remaining segments thinning apically. Pronotum about as long as broad, slightly widened posteriorly, sides straight and gently reflexed, hind margin subtruncated and angle briefly rounded, median sulcus distinct; prozona weakly convex and metazona depressed. Elytra present as narrow, ovate, lateral flaps on mesonotum. Metanotum with hind margin broadly emarginate. Legs typical of the genus. Abdomen narrowed anteriorly, tergites convex, finely punctulated, sides of segments 6 to 9 convex posteriorly, striate. Penultimate sternite transverse, narrowed posteriorly, hind margin rounded or subrotundate with slight emargination in middle. Ultimate tergite smooth, transverse, disc weakly convex, median sulcus faint and laterally above with a raised longitudinal fold, hind margin trisinate. Forceps with branches subcontiguous and stout at base, tapering apically, left branch almost straight, incurved in apical 1/4, right branch strongly incurved in apical 1/3 and slightly crosses over left branch,
apices hooked with tip pointed, trigonal above in basal 1/3, afterwards depressed, internal margin finely crenulated. Genitalia with parameres a little over twice as long as broad, external apical angle along with apical margin convex, inner apical angle obtuse; oblique membrane narrow; distal lobe with chitinous denticulated pads.

Female: Agrees with males in most characters except that sides of abdominal segments smooth; forceps with branches contiguous, straight and tapering apically.

**Types**: Holotype Male, Allotype Female, Paratypes: 1 Male, 1 Female & 1 nymph deposited in Z.S.I.

**Distribution**: India: Maharashtra.

**Remarks**: Amongst the Indian species it can be easily separated by the presence of abbreviated elytra as narrow, ovate lateral flaps.

In addition to above type material, a Male specimen from India: Maharashtra, Poona, 3 km from Sinhgad, 23.v.1979 (*M.S. Pradhan* coll.), det. by Dr. G. K. Srivastava, is also preserved in the collections of Z.S.I.
**Gonolabis punctata** (Srivastava)
(Figs. 173–178)

**Male**: General colour dull blackish to reddish brown. Legs testaceous yellow. Finely punctate all over the body including elytra.

Head triangular, longer than broad, sutures faint, hind margin straight; eyes much smaller than post-ocular area in length. Antennae 17–segmented, stout, 3rd longer than 4th and 5th but equal to 6th, remaining gradually increasing in length distally. Pronotum finely punctate, slightly broader than long, anteriorly straight, laterally straight but diverging posteriorly, hind angles well rounded and margin subtruncate. Elytra and metanotum same as in the preceding species. Abdomen convex, very slightly enlarged in middle, sides of segments obtuse angled posteriorly, ecarinate, often rugosely punctate. Penultimate sternite triangular, obtusely rounded posteriorly, finely punctate, pubescent along the posterior margin. Ultimate tergite transverse, gently contracted posteriorly, sparsely punctate, median sulcus deep, hind margin straight, laterally oblique, gently sinuate. Forceps weakly asymmetrical, remote and trigonal at base with a ridge in basal one fourth only, afterwards depressed, tapering, right brach more incurved than the left, apices gently hooked and pointed, inner margin with a faint tooth at basal one fourth only. Genitalia as seen in fig. 177.

**Female**: Agrees with male in most characters except that the sides of abdominal segments rounded and forceps almost symmetrical.

**Measurements**: (in mm)

**Types**: Holotype Male, Paratypes: 12 Males, 26 Females and 75 nymphs deposited in MZM.

**Paratypes**: 2 Males, 2 Females and 2 nymphs deposited in ZSI.

**Distribution**: India : Tamil Nadu, Shevroy Hills, 4500 ft.

**Remarks**: This species resembles closely with _Anisolabella greeni_ (Burr) in having the whole body punctate but the shape of parameres are quite distinctive. The latter was originally described from Sri Lanka and probably it does not occur in India.
Perhaps all other records of *E. greeni* from India (Burr, 1914, Hebard, 1923) are referable to this species.

**Gonolabis krishnappai** sp. n.  
(Figs. 179–183)

Male : General colour shining brownish black; mouth parts, legs and sides of pronotum and 15th antennal segment pale yellow or brown.

Head longer than broad, frons and occiput weakly raised, in middle with microreticulations, sutures faint, hind margin emarginate in middle. Eyes small, shorter than post ocular area. Antennae 17 (+?) segmented; 1st stout, about as long as the
Figs. 179-183: *Gonolabis krishnappai* sp.n., Holotype Male; 179. Anterior portion of body except ultimate tergite and forceps; 180. Penultimate sternite; 181. Ultimate tergite and forceps; 182. Genitalia; Paratype Female; 183. Ultimate tergite and forceps.

distance between anteninal bases; 2nd short, about as long as broad; 3rd long and slender; 4th stouter and shorter than 3rd; 5th almost equal to 4th; 6th onwards gradually increasing in length distally; a few apical ones thin and rod shaped. Pronotum smooth, anteriorly as broad as head, gently widened posteriorly, lateral margin straight and gently reflexed; hind margin rounded; prozona convex, weakly differentiated from depressed metazona, median sulcus distinct. Elytra smooth, abbreviated, narrowed at base, exposing a broad scutellum, posteriorly forming a broad lobe, meeting along the middle line. Wings absent. Legs typical of the genus. Abdomen long and cylindrical, slightly enlarged in middle, tergites convex, punctulate, sides of segments 7th to 9th convex posteriorly, punctuated. Penultimate sternite transverse, smooth, narrowed posteriorly, hind margin convex in middle. Ultimate tergite transverse, obscurely punctuated, gently depressed in middle posteriorly, hind margin trisinuate, laterally
oblique. Pygidium vertical, narrowed posteriorly with hind margin straight. Forceps with branches remote at base, attenuated posteriorly, almost straight in basal two thirds, afterwards right branch gently and left branch strongly incurved, apices gently hooked, in basal one fourth above trigonal, afterwards depressed, internal margin smooth, except for a small triangular tooth at basal one third. Genitalia with parameres one and half times longer than broad, square shaped, all margins straight, except internal concave, distal lobes with faintly denticulated pads.

Female: Agrees with males in most characters except that the penultimate sternite obtuse in middle posteriorly: ultimate tergite narrowed posteriorly and forceps simple and straight.

Measurements: (in mm)

Material examined: India: Karnataka: Chikmagalur Dist., Mudegera, ca 648 m, ex leaf litter, Holotypes Male (genitalia mounted between two coverslips and pinned with the specimen), Paratype Female, 20. vi. 1987 (S. Krishnappa); deposited in the Z.S.I.

Remarks: This species comes very close Gonolabis punctata (Srivastave) but differs by the shape of parameres in being square shaped, gently broader apically (vs narrower in apical one third in G. punctata), tip represented by a small point (vs obtusely rounded) and apical margin straight (vs oblique and convex).

Gonolabis nilgiriensis (Srivastava)
(Figs. 184-189)

Male: General colour blackish brown, legs testaceous brown.

Head triangular, convex, smooth, sutures fine but distinct. Eyes much shorter than post-ocular area in length. Antennae 17-segmented, 1st equal to 2nd to 4th together; 3rd slightly longer than 4th and equal to 5th, remaining segments long, slender, each gently narrowed basally, gradually increasing in length distally. Pronotum as long as broad, anterior and lateral margins straight, flat, posteriorly subtruncated.
Figs. 184-189: *Gonolabis nilgiriensis* (Srivastava), Male; 184. Anterior portion of body; 185. A few basal antennal segments; 186. Posterior half of penultimate sternite; 187. Ultimate tergite and forceps; 188. Genitalia; Female; 189. Ultimate tergite and forceps.

and gently widened, median sulcus faint; prozona weakly raised. Elytra same as in *G. penicillata* (Borelli). Metanotum transverse, finely punctulate, broadly emarginate posteriorly. Abdomen finely punctulate, enlarged in middle, sides of segments posteriorly acute, carinate on 5th to 7th only. Penultimate sternite obtusely rounded posteriorly, manubrium twice as long as the sternite and dilated at apex. Ultimate tergite sparsely punctate, transverse, gently contracted posteriorly, hind margin in middle subtruncate, laterally oblique and emarginate, median sulcus distinct in anterior half only. Forceps subcontiguous, trigonal in basal 1/3, gradually tapering apically, left branch almost straight in basal two thirds, afterwards incurved, right branch strongly incurved at about middle and crossing over the left, apices gently hooked, internally with a faint tooth at about basal one fourth, otherwise unarmed. Genitalia as seen in fig. 188.

Female: Agrees with male in most characters except that the sides of abdominal segments convex and ecarinate and forceps somewhat symmetrical.

Types: Holotype Male, Paratypes: 9 Males, 10 Females and 2 nymphs deposited in MZM.

Paratypes: 2 Males and 2 Females deposited in ZSI.

Distribution: India: Tamil Nadu, Nilgiri Hills, Naduvatum, 6000 ft.

Genus *Apolabis* Burr

Male genitalia with parameres three times longer than broad, broadest at or near base, gradually narrowed apically, tip may be produced into obtuse point or acuminate; distal lobes with or without virga.

Type species: *Forcinella hottentota* Dohrn, 1867.

Distribution: Oriental, Ethiopian, Neotropical and Australian Regions.

Remarks: At present only four species are known occur in India, of which three are distributed in Peninsular India and one is found in N.E. India (Arunachal Pradesh and Tripura).
Key to species (on Males only)

1(2). Body thickly pubescent; elytra abbreviated in the form of a narrow, ovate lateral flaps on mesonotum .................................................. A. aborensis (Burr)

2(1). Body not thickly pubescent, occasionally short fine pubescence present on abdomen; elytra abbreviated, narrowed strongly at base, in apical half dilated into broad lobes which meet along the median line

3(4). Sides of abdominal segments ecarinate; penultimate sternite broadly rounded posteriorly ................................................................. A. castetsi (Bormans)

4(3). Sides of certain abdominal segments with a median carina; penultimate sternite narrowed posteriorly, feebly obtuse in middle

5(6). Parameres with external and internal margin undulate and tip gently incurved ........................................................................ A. genitalis (Kapoor)

6(5). Parameres triangular, external and internal margins straight and tip straight and pointed ................................................. A. ramachandrai (Ramamurthi & David)

*Apolabis aborensis* (Burr)

(Figs. 190–194)

**Male**: General colour reddish brown, often shaded with black in parts, antennae, sides of pronotum and legs yellowish brown. Form moderately depressed, thickly pubescent with long and short hairs.

Head about as long as broad, triangular, smooth, frons weakly raised and occiput comparatively depressed, sutures fine, hind margin straight. Eyes black, not very prominent, much shorter than the post-ocular area. Antennae 15–segmented or more,

1st stout, expanded apically, about as long as the distance between antennal bases; 2nd short; 3rd long and slender; 4th and 5th, both shorter than the 3rd; 6th almost equal to 3rd, remaining gradually increasing in length and each thinning apically. Pronotum slightly longer than broad, laterally a little reflexed and parallel, posterior margin feebly rounded, disc flat, pro- and metazona weakly differentiated, median sulcus faint. Elytra present as narrow, ovate flaps on the sides of mesonotum. Metanotum transverse and broadly emarginate posteriorly. Sternal plates typical of the genus. Legs normal, hind tarsi with 1st segment slightly longer than the 2nd and 3rd together, clad with fine pubescence and a row of thick chitinous hairs on underside. Abdomen weakly depressed, punctate, gradually expanded posteriorly, sides of segments 7th to 9th rugosely punctate, acute angled posteriorly, an oblique carina present on the segments 7th to 9th only but carina on 9th segment sometimes weak. Penultimate sternite narrowed posteriorly with margin rounded. Ultimate tergite
transverse, punctuation faint and sparse, pubescence wanting, gently narrowed posteriorly with hind margin between the branches of forceps straight and above oblique and emarginate, laterally above with a weak longitudinal fold, median sulcus faint. Forceps contiguous or sub contiguous, trigonal in basal 1/3, afterwards depressed, tapering, almost straight in basal 1/3, thence incurved with right branch more strongly so, apices gently hooked and pointed. Genitalia with parameres three times longer than broad, broadest at base, narrowing apically with tip acute; distal lobes without any discernible virga.

Female: Agrees with male in most characters except that the penultimate sternite obtuse posteriorly; ultimate tergite comparatively more narrowed posteriorly and forceps almost symmetrical and less incurved in apical 1/4.

Measurements: (in mm)

Types: Burr’s (1913b) original description of the species was based on 2 Males, 5 Females from Rotung, 1400 ft., including the Nomotype Male; 1 Female, 1 nymph from Janakmukh, 600 ft., and 1 Males, from Dibrugarh.

Of these Nomotype (= Holotype) Male, 4 Females (= Paratypes) from Rotung and 1 Female, 1 nymph (= Paratypes) are preserved in Z.S.I. and 1 Female (= Paratype) is in the collections of BMNS.

1 Male from Dibrugarh has been designated as the Holotype of *Anisolabella carinatus* (Srivastava, 1987a).

The fate of 1 Male from Rotung, however, is not known. Perhaps, it may be, in the collections of BMNH since a part of the Indian Museum (now Z.S.I.) collection is available there.

Distribution: India: Arunachal Pradesh (Siang dist., Roing; Lohit dist., Deopani and Tirap dist., Hornbill, Firm Base and Namdapha); Assam (Janakmukh) and Tripura (Bramcharra, Teliamura).

Remarks: This species can be easily separated from the other Indian species of the genus in having strongly pubescent body and the elytra as narrow, lateral, ovate flaps on mesonotum.

Besides, it is interesting that this species is confined to the Hills of NE India whereas the remaining three are endemic to Western Ghat Hills in Peninsular India.

*Apolobis castetsi* (Bormans)
(Figs. 195–200)

Male: General colour dark brownish black to light blackish brown; antennae and legs yellowish brown, often shaded with black in parts.

Head triangular, slightly longer than broad, frons raised, feebly punctulate, sutures faint, hind margin slightly emarginate in middle. Eyes small, about 1/3 as long as the post-ocular area. Antennae 14-segmented; 1st stout, gently expanded apically, about as long as the distance between antennal bases; 2nd short; 3rd long and slender; remaining stouter; 4th shorter than the preceding and 5th almost equal to 3rd; 6th onwards gradually increasing in length excepting a few pre-apical ones slightly shorter. Pronotum slightly longer than broad, smooth sometimes a trifle widened posteriorly, median sulcus faintly marked, hind margin subtruncate, prozona and metazona not well differentiated. Elytra abbreviated, narrowed strongly at base exposing a large transverse scutellum, posteriorly widened and meeting along the middle line, obscurely punctulate. Metanotum transverse, obscurely punctulate and finely pubescent, hind margin broadly emarginate. Prosternum three times longer than broad, anteriorly convex, feebly narrowed between fore-coxae, hind margin truncate. Mesosternum about as long as broad, hind margin briefly convex. Metasternum transverse, slightly narrowed beyond hind coxae with hind margin truncate. Legs long, slender tarsi with 1st segment slightly longer than the combined length of 2nd and 3rd segments. Abdomen spindle shaped, finely punctulate, convex, sides of segments 5th to 9th angulate posteriorly but ecarinate, only obscurely striate sometimes. Penultimate sternite transverse, triangular, broadly rounded posteriorly with slight emargination in middle, obscurely punctate. Ultimate tergite transverse, narrowed posteriorly, gently sloping backwards, smooth, hind margin straight in middle, oblique laterally above the bases of forceps, median sulcus faint and short. Forceps with branches subcontiguous, expanded at base, tapering apically and incurved in apical 1/2, at base above with a blunt ridge, afterwards branches depressed, internal margin obscurely crenulate. Genitalia with parameres broadest at base, about four times longer than broad, apices acuminately pointed; distal lobes without virga.

Female: Agrees with males in most characters except that the sides of abdominal segments obtuse or convex; penultimate sternite obtusely triangular posteriorly and forceps simple and straight.

**Types**: Type Male and Female of *Carcinophora castetsi* Bormans, 1897, not known.

Syntype: Males, Females of *Euborellia astruci* Burr, 1910 in BMNH. Burr (1910) mentions several specimens only which could be treated as Syntypes.

Syntype Males of *Apolabis mnemosyne* Menozi, 1929 not known.

**Distribution**: India: Tamil Nadu, Madura Dist., Kodaiknal and Shembaganur.

This species is confined in the above said localities. It should be included in the list of endangered species.

**Remarks**: It occurs in a variety of habitats, such as under stones close to water bodies and under bark of logs and stems of trees.

Although viable populations are available but within a restricted area as stated above.

*Apolabis genitalis* (Kapoor)

(Figs. 201–209)

Male: General colour shining dark brownish black; antennae with basal two segments and legs dark brown.

Head slightly longer than broad, smooth, frons moderately raised, sutures fine but distinct, hind margin emarginate. Eyes shorter than the post-ocular area. Antennae 17–segmented, 1st stout, gently expanded apically, slightly longer than the distance between antennal bases; 2nd small, transverse; 3rd long, slender, gently expanded apically; 4th stout, only slightly longer than broad; 5th stout, longer than 4th but equal to 3rd, remaining stout and each gradually increasing in length excepting a few apical ones slightly shorter and thin. Pronotum slightly longer than broad, smooth, anteriorly straight, gently widened posteriorly with hind margin gently convex, sides depressed, median sulcus faint, prozona moderately convex and well differentiated from flat metazona. Elytra abbreviated, smooth, narrowed at base, exposing a transverse scutellum, broadened apically and meeting along the median line. Metanotum faintly punctulate with hind margin broadly emarginate. Sternal plates typical of the genus. Legs moderately long, hind tarsi with 1st segment slightly longer than the combined length of 2nd and 3rd segments. Abdomen spindle shaped, moderately convex, punctulate, covered with short yellow pubescence, on the sides of tergites above with three lobate, smooth patches arranged in the form of a triangle,
sides of segments 6th to 9th, rugosely punctate, acute angled posteriorly and carinate; on 5th faint convexity present. Penultimate sternite punctulate, obtusely triangular posteriorly. Ultimate tergite obscurely punctulate, transverse, moderately convex, hind margin between branches of forceps straight and above sinuate and oblique. Pygidium vertical, narrowed posteriorly. Forceps subcontiguous, expanded at base, tapering apically, almost straight in basal 2/3, afterwards incurved, apices gently hooked and pointed, in basal 1/3 trigonal with a blunt ridge above, internally at basal
1/3 with a faint tooth. Genitalia with parameres three times longer than broad, narrowed apically, internal and external margin undulate, tip slightly incurved; distal lobes with a short chitinous rod.

Female : Agrees with males in most characters except that the sides of abdominal segments convex, ecarinate, finely punctulate; ultimate tergite more strongly narrowed posteriorly and forceps simple, contiguous and straight.

*Types* : Holotype Male deposited in IARI.

*Distribution* : India : Kerala, Thekkaday, 885 m. Known only from the Type locality.

*Remarks* : This species appears to be closely related to *A. castetsi* (Bormans) but differs, in male, by its slightly larger size; sides of abdominal segments rugose with a longitudinal carina on 6th to 9th only; shape of penultimate sternite obtusely triangular posteriorly and the apical portion of parameres in being slightly incurved.

*Apolabis ramachandrai* (Ramamurthi and David)
(Figs. 210–214)

Male : General colour dark brownish black, head on frons in part, pronotum and elytra shining reddish; antennae and legs light brown.

Head longer than broad, weakly convex, micro-sculptured, sutures obsolete, hind margin emarginate. Eyes prominent, only slightly shorter than the post-ocular area. Antennae (in Holotype Male with 15 segments on the right and 18 on the left remaining) 1st stout, gently expanded apically, about as long as the distance between antennal bases; 2nd short; 3rd long and slender; 4th about as long as broad; 5th slightly longer than broad but both shorter than the 3rd; 5th onwards segments gradually increasing in length and thinning. Pronotum longer than broad, gently widened posteriorly, sides and anterior margin straight, hind margin briefly rounded, prozona weakly raised, metazona gently depressed, median sulcus faint but complete. Elytra abbreviated, near base narrowed, exposing a large transverse scutellum, posteriorly
enlarged, meeting along the median line, smooth. Metasternum transverse, punctulate, hind margin broadly emarginate posteriorly. Sternal plates and legs typical for the genus. Abdomen finely punctulate, gradually enlarging posteriorly, each tergite above laterally with three smooth lobular patches, arranged into a triangle, sides of segments rugosely punctulate, segments 7th to 9th acute angled posteriorly with a faint carina and segments 5th and 6th obtuse posteriorly with a small tubercle. Penultimate sternite triangular with hind margin obtusely produced in middle. Ultimate tergite transverse, sparsely punctulate, moderately convex, narrowed posteriorly, hind margin between the bases of forceps straight and above the branches concave and oblique. Forceps subcontiguous, dilated at base, afterwards tapering, almost straight in basal half, thence gently curved with apices pointed and hooked, at base above trigonal with a ridge present in basal 1/4; internally left arm provided with a small tooth near base and right one with a feeble sinuation, afterwards obscurely crenulate. Genitalia

with parameres roughly triangular, narrowed apically with tip pointed, distal lobes with a short chitinous rod.

Female: Unknown.

*Type*: Holotype Male with the author.

*Distribution*: India: North Malabar, Taliparamba.

*Remarks*: Through the courtesy of Sri B. N. Ramamurthi the Holotype Male, without male genitalia, was available for study.

On the basis of the shape of elytra this species comes close to *A. castetsi* (Bormans) and *A. genitalis* (Kapoor) but differs from both by its larger size and the shape of parameres which are triangular with all margins straight and tip narrowed and pointed.

**Genus Anisolabis** Fieber

Build slender or stout. Mesosternum convex posteriorly. Metasternum produced between hind coxae with hind margin truncate. Male genitalia with parameres five to seven times longer than broad, parallel sided or slightly dilated in middle or at base, tip obtuse, virga present or absent.

*Type species*: *Forficula maritima* Bonelli, in Gené, 1832.

*Distribution*: All regions.

*Remarks*: Srivastava (1999) has redefined the various genera of Anisolabidinae on the shape of male parameres. This genus can be separated from *Carcinophora* Scudder, in having the tip of parameres obtuse.

At present only five species are known from Indian subcontinent of which three are reported from India and two from Sri Lanka. The specimens recorded by Brindle (1971) as *Euborellia kudagae* from Sri Lanka are referable to *Euborellia annulipes* (Lucas).

The status of *A. gaudens* Burr, is doubtful since it is known by females only.

*Rejected records*: The record of *Anisolabis maritima* (Bonelli) from South India by Burr (1914) and Steinmann (1981) are either based on females or nymphs, are doubtful (Srivastava, 1991).

According to Brindle (1977) the record of *Anisolabis dubronii* (Kirby) and *A. kudagae* Burr from India by Gangola (1968) are erroneous.

**Key to species (based on males only)**

1(4). Size larger (15.5 mm or more)

2(3). Genitalia with parameres narrow, about four times longer than broad, almost of uniform width with tip acute .............................................. *A. rubella* Brindle

3(2). Genitalia with parameres broad, about two times longer than broad; broadest in middle, narrowed apically with tip obtuse ...................... *A. kudagae* Burr

4(1). Size smaller (7.8–10.3 mm)

5(6). Sides of abdominal segments 5th to 9th acute angled posteriorly with an oblique carina on 6th to 8th or 9th. ......................... *A. deplanata* Srivastava

6(5). Sides of abdominal segments 5th to 9th obtuse angled posteriorly and ecarinate ........................................................................ *A. bhowmiki* Srivastava

*A. rubella* (Figs. 215–216)

*A. kudagae* (néc Burr, 1901); Burr, 1910, *Fauna British India, Dermaptera* : 84 (Partim, male from Maskeliya only); Burr, 1915, *J. R. micr. Soc.*, 1915 : Pl. XI, fig. 1 (Male genitalia).

Male: Shining reddish brown; legs yellow; antennae dark brown with basal two and basal 1/2 of 3rd segment yellow.

Head about as long as broad, hind margin scarcely emarginate in middle, sutures fine and distinct, frons tumid. Antennae multisegmented (no details available from the original description and figure shows only basal segments), basal segment stout, gently narrowed basally, shorter than the distance between antennal bases. Eyes distinctly shorter than the post-ocular area. Pronotum impunctate, glabrous, about as long as broad, widened posteriorly. Mesonotum transverse, about twice as broad as long with hind margin truncate. Metanotum transverse, hind margin broadly emarginate. Legs typical of the genus. Abdomen broadened posteriorly, tergites weakly convex, first and second tergites impunctate, remaining punctate, size and density of punctures increasing on posterior tergites; sides of abdominal segments produced but not pointed posteriorly, segments 8–9 rugoso-striate, ecarinate. Ultimate tergite transverse, more or less impunctate, at base on sides rugoso-striate, curved ridge laterally above present, hind margin trisinuate, laterally above bases of forceps oblique. Penultimate sternite missing in the Holotype Male. Forceps with branches stout, almost straight in basal half, afterwards incurved with apices hooked, right branch
more strongly curved, trigonal in basal 1/4 above, inner margin denticulated. Genitalia with parameres narrow, a little above five times longer than broad, tip obtuse; distal lobes without virga or denticulated pads.

Female: Unknown.

Type: Holotype Male deposited in BMNH

Distribution: Sri Lanka (Maskeliya).

Remarks: This species is very close to Anisolabis kudagae Burr, also endemic to Sri Lanka, but differs in having the basal two and basal part of third antennal segment yellowish (vs uniformly coloured in A. kudagae) and genitalia with parameres narrow; a little more than five times longer than broad with tip acute (vs broader, three times longer than broad with tip obtuse).

Anisolabis kudagae Burr

(Figs. 217–223)

General colour blackish brown, abdominal tergites in posterior half reddish brown; antennal segments reddish brown. Build stout.

Male: Head longer than broad, hind margin emarginate in middle, smooth, shining, frons feebly convex, sutures fine but distinct. Eyes shorter than post-ocular area. Antennae with 16 segments or more (in the material examined partly broken off), 1st stout, slightly shorter than the distance between antennal bases; 2nd short, about as long as broad; 3rd long and cylindrical; 4th slightly longer than broad, stouter than preceding; 5th slightly longer than 4th and gently expanded apically, 6th onwards segments gradually thining and increasing in length distally. Pronotum about as long as broad, smooth, anterior and lateral margins straight, latter gently reflexed, gently

widened posteriorly with margin subtruncate; prozona weakly raised and poorly differentiated from flat metazona, median sulcus fine but well marked. Mesonotum transverse, smooth, hind margin truncate. Metanotum smooth, transverse, hind margin broadly concave. Legs typical of the genus; hind tarsi with 1st segment longer than the combined length of 2nd and 3rd segments, clad with a row of thick setae on 1st and fine pubescence on underside of all segments. Abdomen spindle shaped, tergites weakly convex, smooth, sides of segments posteriorly convex and rugose from 6th to 9th only. Penultimate sternite narrowed posteriorly, hind margin in middle with a distinct emargination, a shallow median depression extending from base up to middle of the length present; shallow punctures present basally, in apical half rugosely striate. Ultimate tergite transverse, almost smooth except for one or two linear rugosity, disc moderately raised, laterally above with a short fold, hind margin thickened, lightly concave, above bases of forceps oblique and concave; median sulcus short, distinct in middle. Forceps stout and trigonal in basal one third, afterwards depressed, tapering apically, almost straight in basal 1/3, afterwards incurved, right branch
more strongly with its tip crossing over the left, inner margin finely serrated. Genitalia with parameres three times longer than broad, roughly sigmoid, broad in basal 1/3, narrowed apically, distal lobes without virga or teeth.

Female: Agrees with male in most characters except that abdominal tergites feebly punctate; penultimate sternite obtuse in middle posteriorly and forceps simple and straight.

*Types*: Syntypes 1 Male, 1 Female in BMNH.

*Distribution*: Sri Lanka: Kudaga, Hattan; Uva Province; Madulsima and Namunukuli.

*Remarks*: The above description is based on following specimens determined by Burr, as *Anisolabis kudagae* and preserved in the Zoological Survey of India:

One Male labeled as: (i) Indian Mus.; (ii) ♂; (iii) ♂ Namunukuli, Ceylon, July, 1910 and (iv) 6223/16 and genitalia mounted between two coverslips by G. K. Srivastava and attached to the pin.

One Female labeled as: (i) Indian Mus.; (ii) ♂; (iii) Ceylon: Uva P. Madulsima, W.V.I.OI; (iv) 6224/16; (v) *Anisolabis kudagae*—handwritten by Burr.

One Female labeled as: (i) Indian Mus.; (ii) ♀; (iii) Namunukuli, Ceylon, 2–1910; (iv) 6222/16.

Records of *Euborellia kudagae* from Ceylon Brindle (1971) is referrable to *E. annulipes* and *Anisolabis kudagae* by Gangola (1968) from India is doubtful which may be treated as rejected.

Burr (1912) has recorded ‘1 Male from ‘Ceylon, 1861’ which is deposited in NMWA. Sakai (1987, vol. xix p. 2535) has figured perhaps this specimen which measures 9.0 mm, including forceps. The status of this male could be ascertained only after the examination of its genitalia.

This species and *A. rubella* Brindle, are identical in morphological details except for male genitalia.

*Anisolabis deplanata* Srivastava

(Figs. 224–229)

Male: General colour brownish black. Antennae brownish black but lighter than the body colour, 2nd yellowish, 4th or 5th distal segments dirty white. Pronotum along the lateral border yellow. Legs yellow, femora banded with brownish black in basal half. Posterior margin of abdominal tergites lighter in colour.

Head cardiform, smooth, slightly longer than broad, feebly narrowed posteriorly behind eyes, hind margin almost straight, frons convex, sutures obsolete. Eyes small, about half as long as the post-ocular length. Antennae 13–segmented, 1st stout, expanded apically, about as long as the distance between antennal bases; 2nd about as long as broad; 3rd long and slender; 4th and 5th subequal, shorter than 3rd; 6th onwards gradually increasing in length but stouter and expanded apically, a few apical segments shorter and almost globular. Pronotum smooth, about as long as...
broad, gently widened posteriorly, all margins straight, sides feebly reflexed, median sulcus faint, prozona moderately raised and metazona depressed. Meso-and metanotum transverse, smooth, former posteriorly truncate and latter broadly emarginate. Thoracic sternites typical of the genus, mesosternum with hind margin lightly convex and metasternum posteriorly truncate. Legs typical of the genus, hind tarsi with 1st segment slightly longer than the third, claws without an arolium. Abdomen covered with fine, short pubescence, spindle shaped, moderately convex, tergites finely punctulate, sides of segments 5th to 9th acute posteriorly, rugosely punctulate and with an oblique ridge on segments 6th to 8th whereas a faint tubercle only present on segments 4th and 5th posteriorly. Penultimate sternite transverse, obscurely punctulate, posteriorly in middle truncate; manubrium a little over three times longer than the length of the sternite, apex forming a narrow elongated loope. Ultimate tergite transverse, obscurely punctulate, shining, disc in middle feebly depressed with a short median sulcus, hind margin straight between the branches of forceps and laterally oblique. Forceps with branches subcontiguous and trigonal in basal one third; the upper ridge distinct in basal one third, afterwards depressed and tapering apically, incurved in apical one third, right branch more strongly curved, apices pointed. Genitalia with parameres about half as long as pro-parameres and three times longer than broad; distal lobes with small denticulated pads (fig. 229).

Female: Agrees with male in most characters, except branches of forceps simple and straight, tapering apically, comparatively broad.

**Types**: Holotype Male, Paratypes 2 Males of *Anisolabis deplanata* Srivastava in Z.S.I.

Holotype Male, Paratype 1 Female of *Aborolabis martensi* Brindle, in SMF and Paratypes 1 Male and 1 Female in MM.

**Distribution**: India (Arunachal Pradesh) and Nepal (Gorkha dist.)

**Remarks**: On the basis of males this species can be easily discriminated from the other known oriental species of the genus by being smaller in size (7.6–8.5 mm including length of forceps); in having sides of abdominal segments 4th to 9th acute angled, with a median oblique carina on segments 6th to 9th only and a vestige of carina at posterior extreme of angle on 4th and 5th and characteristic genitalia.

**Anisolabis bhowmiki** Srivastava

(Figs. 230–235)

General colour blackish brown, mouth parts, one or two ante-apical antennal segments yellow; legs yellow with basal half of femora banded with blackish brown.

Male: Head slightly longer than broad, shining, frons convex, sutures obsolete, hind margin with slight emargination in middle. Eyes small, about 1/2 as long as the post-ocular area. Antennae (partly broken, on the right side with 5 basal and on the left 15 segments remaining) with basal segment stout, gently expanded apically, slightly shorter than the distance between antennal bases; 3rd long and cylindrical, longer than 4th and 5th; 4th slightly shorter than 5th, subclavate, stouter; 5th slightly stouter than 4th, subclavate; 6th almost equal to 3rd but stouter, narrowed basally.
and gently expanded apically; remaining gradually increasing in length and thinning. Pronotum transverse, gently widened posteriorly, all margins straight, sides gently reflexed, median sulcus faint, prozona weakly raised, hardly differentiated from weakly depressed metazona. Mesonotum and metanotum transverse, former with hind margin truncate and latter broadly emarginate. Elytra and wings absent. Legs typical of the genus. Abdomen gently expanded in middle, convex, lateral tubercles on 3rd and 4th tergites obsolete, sides of segments 5th to 9th obtuse angled posteriorly, ecarinate, rugulosely punctulate. Penultimate sternite obscurely punctulate, transverse, hind margin scarcely emarginate in middle, Ultimate tergite transverse, smooth, shining, sloping backwards, median sulcus distinct, hind margin trisinuate, laterally oblique. Forceps subcontiguous, expanded at base, tapering apically, left branch almost straight, right bent in basal half, apices gently hooked and pointed, trigonal above in basal 1/3, afterwards depressed, internal margin finely serrated, Genitalia with parameres (fig. 235) about twice as long as broad, narrowed apically with tip obtuse; distal lobes with chitinous denticulated pad.

**Female** : Unknown.

**Type** : Holotype Male in ZSI.

**Distribution** : India : West Bengal : Darjeeling dist., Sonada, alt. 1971 m.

**Remarks** : This species comes very close to *Anisolabis deplanata* Srivastava, by its small size but differs in having the sides of abdominal segments 5th to 9th obtuse angled and ecarinate. Besides the shape of parameres in this species is distinctive in being slightly expanded basally.

**Uncertain Species**

*Anisolabis gaudens* Burr

(Figs. 236–237)

Male: Unknown.

Female: General colour shining blackish red, head clear brick red; antennae with basal two segments reddish. Build stout.

Head about as long as broad, convex, sutures faint; antennae 15-segmented, 4th and 5th almost globular; eyes black, shorter than post-ocular area. Pronotum transverse, gently expanded posteriorly with margin subtruncate. Elytra and wings absent. Legs normal. Abdomen smooth, gently widened posteriorly. Penultimate sternite with posterior margin rounded in middle. Ultimate tergite weakly transverse, gently narrowed from middle. Forceps with branches simple, straight, contiguous, trigonal near base, tapering, apices pointed, gently incurved and crossing, inner margin unarmed.

Type: Holotype Female (néc Male) in MNHP.

Distribution: India: Sikkim (Pedong) and Arunachal Pradesh (Siang dist., Rotung).

Remarks: The original description of the species was based on 1 Female (not Male as stated) from Bhutan, Pedong. Pedong is now included under Sikkim.

The record of the species from Meghalaya by Biswas, Lahiri and Ghosh (1975) is doubtful since it is based upon nymphs, not males as reported.

Subfamily BRACHYLABIDINAE

Apterous. Build slender, elongated, legs long, tarsi with middle segment slightly longer than broad. Eyes longer, equal or shorter than the post-ocular area and distance
between antennal bases or first basal segment. Antennae with 1st segment longer than the distance between bases; 2nd short, about as long as broad; 3rd long and slender, slightly or distinctly longer than broad; 4th stouter, a trifle longer than broad; slightly shorter or equal to preceding. Lateral margin of mesonotum with a sharp carina or convexity, often dying out posteriorly. Abdomen fusiform or narrowing apically. Ultimate tergite with hind margin trisinuate, laterally oblique, often above the bases of forceps projecting as a triangular or obtuse lobe. Forceps generally cylindrical, less commonly flattened along the inner margin, generally, in both sexes, similar. Pygidium vertical, hidden. Male genitalia with parameres narrowed apically, distal lobes with chitinoid rods or teeth, proparameres narrow.

Type genus: Brachylabis Dohrn, 1864.

Distribution: In the tropical parts of the world.

Remarks: Species generally occur in soil, especially in dead and decaying leaf litter or vegetative matter. Due to their secretive habits and general body color similar to their surrounding coupled with small size they escape the notice of general insect collector.

It is advisable to collect several specimens for each species which would increase the possibility of getting both the sexes which are generally similar externally. Often it is difficult to locate sexes on the basis of tergal counts since these are telescoped. In such cases the dissection of genitalia is essential to establish the gender.

In the present work the interpretation of the family is after Steinmann (1989).

Key to the genera
(partly modified after Steinmann, 1989)

1(4). Eyes, in both sexes, prominent, may be about as long or shorter than the basal segment or always equal or longer than the distance between antennal bases

2(3). Fourth antennal segment slightly longer than broad; male genitalia especially proparameres long, narrowed posteriorly......................Metisolabis Burr

3(2). Fourth antennal joint about as broad as long; male genitalia, especially proparameres comparatively short and not so strongly narrowed posteriorly

4(1). Eyes, in both sexes, shorter than the basal antennal segment and distance between antennal bases........................................Brachylabis Dohrn

Genus Metisolabis Burr

Metisolabis Burr, 1910, Fauna British India, Dermaptera : 108 (Type species: Brachylabis voeltzkowi Burr, 1908); Burr, 1910, Trans ent. Soc. Lond., 1910 : 196; Burr, 1911, Genera Insect., 122 : 42; Townes, 1945, Ann. ent. Soc. Am, 38 : 351; Popham and Brindle, 1966, Entomologist, 99 : 245 (proposed synonymy with Isolabis Verhoeff, 1902); Brindle, 1966, Trans. R. ent. Soc. Lond., 118 : 233 (revision and key to species); Brindle,
General colour black to brownish black, body coriaceous and finely punctate. Antennae stout, basal segment longer than the distance between antennal bases; 2nd about as long as broad; 3rd generally twice as long broad; 4th slightly longer than broad. Eyes prominent, longer than the distance between antennal bases and shorter or equal to basal antennal segment. Mesonotum laterally with a distinct carina or convexity, often dying out posteriorly.

Type species: *Brachylabis voeltzkowi* Burr 1908.

Distribution: Ethiopian, Malagasy and Oriental Regions.

Key to species (based on males)

1(2). Legs uniform black or brownish black; mesosternum laterally with a distinct convexity, dying out posteriorly; forceps stout, strongly incurved .................

................................................................. *M. bifoveolata* (Bolivar)

2(1). Legs yellowish with apical third of femora banded with black; mesosternum laterally with a sharp and complete carina or ridge; forceps slender, almost straight in basal 2/3, afterwards gently incurved ............ *M. caudelli* (Burr)

*Metisolabis bifoveolata* (Bolivar)

(figs. 238–241)

*Ctenisolabis bifoveolata* : Burr, 1911, *J. Asiat. Soc. Beng. (N.S.)* 7: 780 (Shembaganur, Madura dist.).

Figs. 238-241: *Metisolabis bifoveolata* (Bolivar), Male; 238. Dorsal view; 239. Penultimate sternite; 240. Genitalia; Female; 241. Ultimate tergite and forceps.

Male: Colour black; antennae dark brown, distal segments slightly blackish; legs dark brown; punctate all over the body except forceps; golden yellow pubescence present.

Head triangular, caudal margin straight, frons tumid, sutures distinct. Eyes large, black, slightly longer than post-ocular area. Antennae 14–segmented, stout, basal segment narrowed at base and expanded at apex, long, equal to segments 2nd to 5th together; 2nd small; 3rd twice as long as broad; 4th long, only slightly longer than broad but shorter than 3rd; 5th slightly longer than 3rd; rest gradually increasing in length distally. Pronotum longer than broad, widened posteriorly, all margins straight, sides slightly raised, hind angles rounded, median suture distinct, with a pair of longitudinal patches of smooth areas on either side; prozona and metazona not differentiated. Mesonotum with a lateral convexity, strongly curving posteriorly, hind margin subtruncated. Metanotum transverse, concave posteriorly. Abdomen strongly
convex, narrowed anteriorly and posteriorly, dilated in middle, lateral tubercles on 3rd tergite blunt and 4th weakly developed; a smooth rounded patch below these folds present on 4th tergite, sides of segments rounded. Penultimate sternite transverse, rounded posteriorly with a small emargination in middle. Ultimate tergite transverse, sloping backwards in middle, sides straight, hind margin trisinuate, laterally oblique, above the root of forceps with a obtuse lobe. Forceps with branches remote and somewhat dilated at base, strongly or weakly incurved, tapering posteriorly, apices pointed and meeting or crossing. Genitalia with parameres narrowed apically tip pointed; distal lobes with a distinct tubular rod and a fine virga projecting through it (fig. 240).

Female: Agrees with male in most characters except penultimate sternite with posterior margin rounded and forceps less incurved with inner margin at base crenulate.

Measurements: (in mm)

Type: Type Male in MNHP (Steinmann, 1989a).

Distribution: India: Tamil Nadu (Tiruchirapalli), Shembaganur (Madura dist.), Kodaikanal, Annamalai Hills (Cinchona, 3500 ft & Valparai) and Palinis (Maryland, Tigershola, 1600 ft.).

Remarks: Some variation have been noted in the relative length of antennal segments especially from 4 to 6 segments. Eyes are generally longer than the post-ocular area but sometimes these are comparatively less prominent and forceps, in males, may be strongly or weakly incurred.

Metisolabis caudelli (Burr)
(Figs. 242–245)

Brachylabis punctata (née Dubrony); Bormns, 1894, Annali Mus. civ. Stor. nat. Giacomo Doria, (2) 14 : 386 (Part of the specimens from Burma).

Figs. 242-245: Metisolabis caudelli (Burr), Male; 242. Dorsal view; 243. Penultimate sternite; 244. Genitalia; Female; 245. Dorsal view.

Ctenisolabis aciculata Steinmann, 1983, Revue suisse Zool., 90 (3) : 545, fig. 3 (1 Female; India, Meghalaya, Khasi Hills).

Ctenisolabis loebli Steinmann, 1983, Revue suisse Zool., 90 (3) : 546, fig. 4 (1 Female; India, W.B. : Darjeeling).

Brachylabis philetas (néc Burr, 1901), Steinmann, 1983, Revue suisse Zool., 90 (3) : 546 (1 Male, (néc Female); India, W.B. Darjeeling Dist., Algarah).

General colour dark blackish brown; antennal segments, mouth parts, apical third of femora, whole of tibia and tarsi yellowish. Body covered with fine pubescence.

Male: Head triangular, longer than broad, punctate, frons convex, hind margin almost straight. Eyes about as long as post-ocular area or distinctly longer. Antennae (partly damaged) 12–segmented or more, 1st narrowed at base, longer than the distance
between antennal bases; 2nd small; 3rd long, slender, slightly or distinctly longer than broad; 4th a trifle longer than broad and slightly shorter than 3rd or almost equal; 5th longer than broad, gently narrowed basally, generally longer than 3rd, remaining segments gradually increasing in length distally. Pronotum more strongly punctate than the head, longer than broad, anteriorly wider than the head, anterior margin and sides straight, weakly reflexed in middle, strongly diverging posteriorly, postero-lateral angles rounded and margin subtruncate, median sulcus distinct on prozona, on either side of it with a faint depression; prozona and metazona raised, little differentiated. Mesonotum punctate, transverse, laterally with a distinct raised carina, hind margin straight. Metanotum transverse, laterally ecarinate, punctate, hind margin broadly emarginate. Legs long and slender, hind tarsi with basal segment almost equal to the combined length of 2nd and 3rd. Abdomen spindle shaped, punctate, convex, sides of segments posteriorly convex, lateral tubercles on 3rd and 4th tergites weakly marked. Penultimate sternite punctate, transverse, broadly rounded posteriorly with a distinct median emargination, manubrium short, about half as long as the sternite, slightly narrowed apically. Ultimate tergite transverse, sparsely punctate as compared to abdominal tergites, sloping backwards in middle posteriorly, sides straight, posterior margin trisinuate, laterally oblique, above the base of forceps projecting in the form of a triangular or obtuse lobe. Pygidium scarcely visible from above, vertical, narrowed posteriorly. Forceps with branches cylindrical, remote, regularly incruved, tapering from base to apex with apices touching or subcontiguous, straight, tapering, gently incurved in apical one third and crossing, apices pointed. Genitalia as seen in fig. 244.

Female: Agrees with males in most characters except that the ultimate tergite strongly narrowed posteriorly and forceps simple and straight.

Distribution: India (North-Eastern Himalayas and Khasi Hills) and Myanmar. Besides, the record of this species from Borneo (Borelli, 1932) needs checking.

Type: Holotype Male of *Brachylabis caudelli* Burr in BMNH.

Holotype female of *Ctenisolabis aciculata* Steinmann and Holotype Female of *Ctenisolabis loebli* Steinmann in MHNG.

Holotype Male and Paratype Female of *Metisolabis fulgens* Steinmann in HNAB.

Remarks: Above synonymy and intraspecific variations have been discussed in detail by Srivastava (1993a).

The description of *Metisolabis fulgens* Steinmann from Myanmar fits well within the variational range of this species and treated as a synonym.
Genus **Ctenisolabis** Verhoeff

Very similar to preceding genus in general appearance and texture of the body. Apterous. Antennae with 4th segment, subclavate, stout, about as long as broad. Pronotum generally longer than broad. Mesonotum laterally with a carina or convexity, often dying out posteriorly. Metanotum transverse with hind margin straight. Legs long and slender. Abdomen cylindrical, fusiform, tergites generally punctate. Ultimate tergite transverse, trisinuate along the posterior margin, above the bases of forceps produced into a narrow lobe. Male genitalia with parameres strongly narrowed apically, virga short and tubular.

**Types**: *Ctenisolabis togoensis* Verhoeff, 1902.

**Distribution**: Oriental, Etiopian, Malagassy and Neotropical Regions.

**Remarks**: At present two species, namely *C. fletcheri* Burr and *C. pusilla* Steinmann, are reported from the Indian subcontinent. Former occurs in Sri Lanka and India and latter is described, on a female, from Sri Lanka.

In the absence of a male, the status of *C. pusilla* is doubtful.

Both the species are similar in general body colour and shape and can be differentiated only on the basis of body size.

*Ctenisolabis fletcheri* Burr

(Figs. 246–253)

Male: General colour blackish brown; legs yellow with femora apically blackish brown. Covered with fine yellow pubescence and punctate all over the body.

Head longer than broad, frons strongly convex, hind margin almost straight. Eyes prominent, about twice as long as the post-ocular area. Antennae 13–segmented, 1st long, stout, expanded apically, longer than the distance between antennal bases; 2nd
short, about as long as broad; 3rd long, slender, about twice as long as broad; 4th subclavate, stout, about as long as broad, remaining gradually increasing in length and thickness, except a few apical ones. Pronotum longer than broad, expanded posteriorly, median sulcus represented by a small line extending up to the middle, all margins straight, lateral margin gently reflexed. Meso- and metanotum transverse, former with a distinct curved fold laterally, dying out posteriorly. Legs long and slender, typical of the genus. Abdomen spindle shaped, laterally with long pubescence, lateral tubercle on 3rd and 4th tergites feebly marked. Penultimate sternite triangular, hind margin with a emargination in middle, manubrium slightly longer than the sternite, almost of uniform width. Ultimate tergite transverse, sloping backwards, hind margin trisinuate, laterally oblique, above the bases of forceps produced into minute lobe. Forceps long and cylindrical, remote at base, tapering apically, almost straight in a little beyond basal half, afterwards incurved, apices pointed, branches crossing a little before apex, inner margin finely serrated. Genitalia with parameres broader at base, narrowed apically with tip pointed; virga fine, tubular.

Female: Agrees with males in most characters except that the penultimate sternite obtuse posteriorly and forceps simple and straight.

Measurements: (in mm)

Distribution: Sri Lanka and India (Karnataka and Tamil Nadu).

Type: Type Female in BMNH.

It may be mentioned here that Burr (1910, p. 110) in the text mentions ‘Type Female’ but in the legend to fig. 79 it is given as ‘Male Type’. From the figure it appears to be a Female specimen.

Remarks: This species is represented in Z.S.I. Collection by a male from Tamil Nadu, Vandalore, 19.vii.1980 (Dr. K Mathew Coll.) hitherto not reported.

Rejected records: Borelli’s (1926a) record of this species from Tajidobas, Java based upon a female and nymph is doubtful and may be treated as rejected.

Uncertain species

Ctenisolabis pusilla Steinmann
(Figs. 254-255)

Ctenisolabis pusilla Steinmann, 1879, Folia ent. hung., 31 : 216 (Female; Ceylon (Sri Lanka), Kendy Eliya); Steinmann, 1989, Das Tierreich, 105 : 296, fig. 485 (Female Ultimate tergite and Forceps figured); Steinmann, 1989, World Catalogue of Dermaptera : 315.

Female: General colour dark brown, antennae and forceps light brown; legs brown with femora yellowish white apically.

Head about as long as broad, frons convex, sutures distinct, hind margin scarcely emarginate in middle. Antennae 12-segmented, basal segment stout, gently expanded apically, longer than the distance between antennal bases; 2nd short, about as long as broad. Eyes prominent, longer than the post-ocular area. Pronotum slightly longer than broad, lateral and hind margin straight, gently dilated posteriorly, median sulcus distinct. Meso- and metanotum transverse, former with hind margin truncate, laterally carinated and latter ecarinate laterally with hind margin broadly emarginate. Elytra and wings absent. Legs typical of the genus, long, hind leg longer than the combined length of abdomen and forceps. Abdomen convex, broad, in middle, tergites punctate. Ultimate tergite transverse, hind margin emarginate in middle, with posteriorly directed pointed lobe above the bases of forceps. Forceps simple, straight, pointed apically.

Male : Unknown.

Type : Holotype Female in HANB.

Distribution : Known only by the Holotype Female from Sri Lanka.

Remarks : In the absence of a male, the taxonomic status of the species, is difficult to ascertain. It can be separated from C. fletcheri Burr, by its smaller size.

Amongst the other Indian Anisolabid species, it comes closer to Antisolabis formicoides (Burr, 1911b) on the basis of body size but latter has uniformly coloured legs.

Genus Brachylabis Dohrn

Similar in appearance to members of the genera Metisolabis Burr and Ctenisolabis Verhoeff. Eyes small, slightly shorter than the post-ocular area and shorter than the first antennal segment and distance between antennal bases. Antennae with basal segment long, narrowed apically; 2nd short; 3rd long and cylindrical; 4th and 5th subclavate. Head and body punctate. Tegmina wanting or abbreviated; wings absent. Abdomen fusiform, cylindrical. Legs long and slender. Forceps, in males, sometimes incurved, stout or simple and straight in both sexes. Male genitalia with proparameres narrow, apical incision short, paramere acute apically; distal lobes with virga; sclerotised chitinous plates present or absent.

Type species: Forficula chiliensis Blanchard, 1851

Distribution: Neotropical, Ethiopian, Indo-Australian and Oriental Regions.

Remarks: According to Steinmann (1989a) 11 species under this genus are included. In the Indian subcontinent only two species from Sri Lanka are reported. Out of this Brachylabis philetas (Burr, 1901) is so far known by females.

Key to species

1(2). Pronotum transverse ................................................ .... B. formicoides (Burr)
2(1). Pronotum about as long as broad or longer than broad
3(4). Body length about 7 mm; head and pronotum punctate, latter as long as broad; forceps, in male, simple and straight ................... .... B. philetas (Burr)
4(3). Length 9-10 mm; head and pronotum impunctate or almost so, latter longer than broad; forceps, in male, stout and strongly incurved ............................................ ...

Brachylabis philetas (Burr)

The Fauna of India and the Adjacent Countries

Size small (7.25 – 8.5 mm); whole body punctate, with a few stiff hairs.

General colour black; antennae with 2nd segment reddish and 7th & 8th whitish, remaining black.

Male: Head about as long as broad. Eyes prominent but shorter than post-ocular area. Antennae with 1st segment long, stout; 2nd short; afterwards segments rounded, about as long as broad, gradually increasing in length up to 8th and 9th shorter than preceding. Pronotum about as long as broad, slightly widened posteriorly, lateral margin gently reflexed; mesonotum transverse, laterally with a ridge, hind margin straight and metanotum as broad as mesonotum with hind margin broadly emarginate. Legs long, testaceous, femora with a black band; hind tarsi with 1st segment longer than the combined length of 2nd & 3rd. Abdomen fusiform, lateral tubercles on 2nd and 3rd distinct. Ultimate tergite small. Forceps short, slender, remote at base, slightly incurved, meeting at apex.

Female: Agrees with male in most characters except that forceps are simple, contiguous and straight.

**Distribution:** Sri Lanka (Punduluoya).

**Types:** Male and Female in BMNH.

**Remarks:** This species is so far known by its Types. The above description is based upon available literature.

Brindle's (1971) record of the species from Sri Lanka, is referable to *Antisolabis ceylonicus* (Brindle).

**Brachylabis willeyi** (Burr)

(Figs. 256 - 259)

Figs. 256-259: 

Brachylabis willeyi (Burr), Male; 256. Dorsal view; 257. A few basal antennal segments; 258. Genitalia; Female; 259. Dorsal view.

Male: General colour dark blackish brown, shining; apial part of femora, tibia and whole of tarsi yellowish brown.

Head pilose, shallow punctures present near hind margin; longer than broad, convex, sutures obsolete, hind margin with slight emargination in middle. Antennae 14-segmented or more, 1st stout longer than the combined length of 2nd to 4th; 2nd short, about as long as broad; 3rd long, slender, slightly longer than 4th; 4th subclavate; 5th subclavate but longer than the preceding, remaining gradually increasing in length and each strongly narrowed at base. Eyes much shorter than post ocular area; Pronotum longer than broad, obscurely punctate, sides straight, gently reflexed, gently widened posteriorly, hind margin subtruncate, convex, median sulcus faint, prozona and metazona not well differentiated. Mesonotum and metanotum punctate, transverse, former with a lateral incurved fold extending up to middle of the length, a transverse depression present, hind margin faintly emarginate and latter broadly emarginate posteriorly. Legs long, slender, hind tarsi with basal segment almost equal to the combined length of 2nd and 3rd, clad with thick pubescence on underside. Abdomen spindle shaped, tergites deeply punctate, convex, lateral folds on 3rd and 4th tergites distinct, sides of segments convex. Penultimate sternite with hind margin broadly rounded and a faint emargination in middle present. Ultimate tergite
transverse, punctate, hind margin bsinuate, above bases of forceps oblique. Forceps remote at base, strongly incurved, tapering apically, tips gently hooked and pointed, inner margin ventrally with one or two small teeth. Genitalia with parameres three times longer than broad, slightly narrowed apically with tip acuminate; distal lobes with long, thin virga, basal vesicle distinct.

Female: Agrees with male in most characters except that penultimate sternite with hind margin obtusely rounded; ultimate tergite narrowed posteriorly; pygidium distinct, narrowed posteriorly and forceps simple and straight, inner margin serrated for a short distance.

Type: Type Male and Paratype Female in BMNH.

Distribution: Sri Lanka, Central Province: Patipola, Hakgala, Pidurutalagila, 1900 m, 2 miles NW Nuwara – Eliya, Horton Plains, 2000 m, 11 miles SSE Nuwara Eliya and Kandy.

Remarks: The above description of the species is based upon 1 Male and 1 Female determined by Brindle (1971) from Sri Lanka and preserved in the Zoological Institute, Lund, Sweden.

This species can be easily separated from the two other known species from India and Sri Lanka viz., B. formicoides (Burr) and B. philetas (Burr) by its larger size and from the latter further by having head and pronotum smooth or almost so.

According to Brindle (1977) it is a rare species and restricted to Sri Lanka.

*Brachylabis formicoides* (Burr)
(Figs. 260 - 265)

Male: General colour dark brown with shades of black on certain body parts. Antennae (partly broken) with 10th and 11th segments of right and 11th of left; apical part of femora and tibia and tarsi yellow. Body finely punctulate.

Head longer than broad, hind margin rounded with a faint depression in middle, frons convex, sutures obsolete. Antennae 12-segmented, 1st stout, gently expanded apically, longer than the antennal bases and eyes; 2nd short; 3rd long, cylindrical; 4th subclavate, shorter than 3rd; 5th subclavate but longer than preceding, 5th onwards gradually increasing in length, cylindrical. Eyes distinct, shorter than the post-ocular area. Pronotum transverse, gently widened posteriorly, sides straight, hind margin subtruncate, pro- and metazona hardly differentiated, median sulcus faint. Meso- and metanotum transverse, former with hind margin straight, laterally with a curved convexity and latter with hind margin broadly emarginate, without a lateral convexity. Legs long and slender, hind leg longer than the abdomen, hind tarsi with 1st segment equal to combined length of 2nd & 3rd; 2nd twice as long as broad; 3rd longer than 2nd, claw without an arolium. Abdomen fusiform, tergites finely punctulate, convex. Penultimate sternite transverse, hind margin with a small point in middle, manubrium as long as the sternite, slightly narrowed apically. Ultimate tergite, transverse, sides straight, hind margin trisinuate, oblique above bases of forceps. Forceps with branches short, subcontiguous, with a faint ridge above, gently curved with apices pointed and crossing. Genitalia with parameres narrowed apically, external margin with a faint constriction in middle; virga distinct.
Female: Agrees with male in most characters except that ultimate tergite narrowed posteriorly and forceps contiguous and straight.

**Types**: Syntypes Male & Female in BMNH.

Burr (1911b) mentions “Numerous specimens.....” which are not designated as Syntypes but may be treated as such.

**Distribution**: India: Tamil Nadu: Madura dist., Shembaganur, near Kodaiknal.

In the collections of ZSI a female specimen from “India, Tamil Nadu, Madura dist., Borijam Lake, 2000 ft”, det by G. K. Srivastava, not reported earlier, is present.

**Remarks**: It is included under the genus on the basis of basal antennal segment being longer than the distance between antennal bases and lateral convexity on mesonotum.

This species comes close to *B. philetas* (Burr) in body size and having forceps, in males, simple and straight but differs by shape of pronotum being broader than long.

**Subfamily** **ANTISOLABIDINAE**

Head longer than broad; eyes distinctly shorter than the post-ocular area; basal antennal segments shorter or equal to distance between bases of antennae, apical ones slender or stout. Elytra and wings absent, rarely former present in abbreviated form. Legs not slender and long. Mesonotum without lateral ridge or convexity. Abdomen fusiform, depressed. Forceps, in both, sexes simple, in males, sometimes sub-contiguous, slightly curved in apical half.

Male genitalia with proparamere fused along its length, sometimes with a short clevage apically, virga tubular, straight and sclerotized.

**Type genus** *Antisolabis* Burr, 1911.

**Distribution**: Ethiopian, Malgassian, Indo-Australian and Oriental Regions.
Remarks: This subfamily is represented by a single genus containing 32 species spread all over the world of which only two are known from Sri Lanka within the Indian subcontinent.

A. kelangi (Brindle), originally described from Malaysia, is now represented in Sri Lanka as a result of synonymy of Geracodes brincki Brindle, from Sri Lanka under it.

Genus *Antisolabis* Burr

The characters of the family are applicable to genus also.

Generally apterous, sometimes abbreviated elytra present. Basal segment of antennae about as long as the distance between antennal bases; eyes shorter than post-ocular area.

Types species: *Antisolabis myrmecoides* Burr, 1911.

Distribution: Ethiopian, Malgassian, Indo-Australian and Oriental Regions.

**Key to species (bases on males only)**

1(2). General colour blackish; pronotum transverse, parallel sided, genitalia with parameres broader at base, narrowed gradually towards apex, tip acuminate, virga thin, tubular .......................................................... ....... *A. ceylonica* (Brindle)

2(1). General colour yellowish-brown; pronotum longer than broad, sides diverging posteriorly, genitalia with parameres broad in basal two third, narrowed in apical one third with tip pointed, virga thick with sclerotized and denticulated areas ................................................................. ....... *A. kelangi* (Brindle)

*Antisolabis ceylonica* (Brindle)

(Figs. 266-269)

*Nannisolabis philetas* (néc Burr); Brindle, 1971, *Ent. scand. Suppl.*, 1: 221 (10 specimen including, 1 Male, 2 Females, 7 nymphs; Sri Lanka); Sakai, 1987, *Dermapterorum Cat.*, 19: 2327 (Female figure, Manchester only).

Figs. 266-269: *Antisolabis ceylonica* (Brindle), Male; 266. Dorsal view; 267. A few basal antennal segments; 268. Genitalia (after Brindle, 1971); Female; 269. Dorsal view (after Sakai, 1987 and labelled by him as *Antisolabis philetas* Burr but according to Brindle, 1977, p. 456, it is referable to this species).

Apterous. General colour blackish; antennae dark brown; legs yellow except femora of all the legs dark brown at apex to apical one fourth. Head granulose, thorax and abdomen punctate; abdominal tergites less strongly punctate and close to hind margin impunctate. Glabrous, abdomen with short, yellow, depressed and long, dark hairs.

Male: Head about as long as broad, frons convex, sutures faint, hind margin straight. Antennae 10-segmented, stout, basal segment about as long as the distance between antennal bases; 2nd short; 3rd slender, twice as long as broad; 4th globular; 5th onwards segments stout. Eyes shorter than the post-ocular area. Pronotum transverse; parallel sided, hind margin subtruncate. Mesonotum and metanotum transverse, former with a curved ridge separating depressed anterior half from raised posterior half with hind margin straight and latter with hind margin broadly...
concave. Legs long and slender. Abdomen fusiform, lateral tubercles on 3rd and 4th tergites weakly developed, 5th segment with a smooth oval area just posterior to lateral tubercle on 4th tergite. Penultimate sternite posteriorly rounded, with a faint excision in middle. Forceps with branches straight, subcontiguous, gradually tapering backwards, apices gently hooked, inner margin finely serrated. Genitalia with parameres pointed apically, distal lobes with virga slender.

Female: Agrees with males in most characters except that forceps more slender.

**Types**: Holotype Male, Paratypes: 16 Males and 4 Females in MHNG; 2 Males, 2 Females in MM and 2 Males, 1 Female in BMNH.

**Distribution**: Sri Lanka, Central Prov.: Kandy env., 600 m and Malhulla.

*Antisolabis kelangi* (Brindle)

(Figs. 270-275)

General colour yellowish to yellowish brown; mouth parts, palpi and legs yellow; forceps brown. Body punctured and pubescent, hairs yellow, relatively long laterally.

Male: Head longer than broad, cardiform, hind margin emarginate in middle, frons convex. Antennae with 1st segment long, expanded apically, longer than the distance between antennal bases; 2nd short, transverse; 3rd twice as long as broad; 4th one and half times as long as broad; 5th slightly longer; 6th longer than 5th and equal to 3rd; remaining distal segments shorter and broader, about one and half times longer than broad.

Pronotum longer than broad, widened posteriorly, hind margin rounded, median sulcus distinct. Mesonotum transverse, lateral margin ecarinate, hind margin straight. Metanotum transverse, hind margin emarginate. Legs relatively short; femora broadened, especially of anterior legs; tarsi of hind leg with 1st segment equal to 3rd.

Apterous. Abdomen widened in middle, depressed, lateral tubercles on 3rd & 4th tergites hardly visible. Ultimate tergite transverse, smooth above, posterior margin scarcely emarginate in middle, laterally above bases of forceps oblique. Forceps short, cylindrical, tapering apically, tip gently hooked and gently raised upwards, inner margin irregular, but scarcely dentate. Genitalia with parameres narrowed apically, tip pointed; distal lobes with distinct virga and associated with dark, elongated, sclerotized and denticulated areas.

Female : Almost similar to male except for eight visible abdominal segments.

Measurements : (in mm)

Types: Holotype Male, Allotype Female of *Brachylabis kelangi* Brindle, 1969 in BMNH and Paratype 1 Male in MM.

Holotype Male and Allotype Female of *Geracodes brincki* Brindle, 1971 in ZILS.

Distribution: West Malaysia and Sri Lanka.

Remarks: Although *Geracodes brincki* Brindle, has been synonymised by Steinmann (1989) under this species there is need to check the Holotypes of both species.

*Geracodes brincki* has well developed elytra, concealed wings and in male, penultimate sternite, is transverse with a triangular process in the middle of posterior margin.

Penultimate sternite of *Brachylabis kelangi* is not described.

Subfamily ISOLABOIDINAE

Apterous. Size small to medium (7.5 mm to 13.00 mm). Forceps, in males, slender or stout, regularly incurved or straight in basal two thirds, afterwards gently incurved; in females simple and straight. Male genitalia with right distal lobe (penis lobe) atrophied with or without rudimentary virga; left distal lobe enormous with spirally coiled virga; proparameres paired but most of its apical part covered with right distal lobe.

Distribution: Asia Minor to India.

Remarks: The subfamily contains the single type genus.

Genus *Isolaboides* Hincks

Eyes small, shorter than post ocular area. Antennae 18-22 jointed, 1st shorter than the distance between antennal bases. Apterous. Meso- and metanotum ecarinate laterally. Legs with femora thick, hind tarsi with 1st segment almost equal to the combined length of 2nd and 3rd; 2nd distinctly longer than broad, narrow and slightly shorter than 3rd. Pygidium vertical. Genitalia with proproameres paired but genital lobe of right side atrophied and of left side well developed with virga spirally coiled.

Type species: Pseudisolabis kosswigi Burr, 1947.

Distribution: From Asia Minor to India.

Remarks: Paralaboides Steinmann, 1990 was synonymised under the genus by Srivastava (1996).

This genus is included under the family Anisolabididae on the basis of male genitalia possessing paired proproameres and the right distal lobe greatly enlarged whereas the left one vestigial.

Key to the species (based on males)

1(4). Penultimate sternite with hind margin entire; virga large and spirally coiled

2(3). Forceps (in forma macrolabia) stout and abruptly incurved in apical half; Parameres broad, anterior margin oblique, forming an obtuse angle with external margin, coils of virga short and narrow.................I. burri (Borelli)

3(2). Forceps (in forma macrolabia) comparatively thinner, regularly incurved; parameres narrower, broadest at base, gradually narrowing towards apex, coils of virga large and loosely arranged........................................I. immsi (Burr)

4(1). Penultimate sternite posterolaterally with a concavity, virga short and coiled. ........................................................................................................I. rimosus Steinmann

Isolaboides burri (Borelli)  
(Figs. 276-280)

(Male,Female; NE Kashmir – along the road from Gilgit to Srinagar); Burr, 1910, Fauna British India, Dermaptera : 103,fig. 35 (Male in dorsal view); Burr, 1911, Genera Insect., 122 : 39.pl. 3, fig. 4 (head and sternum in ventral view); Bey-Bienko, 1936, Faune de L’URSS, Dermaptera : 106, fig. 30 (Male, dorsal view); Hincks, 1947, Proc. R. ent. Soc. Lond., (B) 16(5-6) : 60, fig. 3 (Male genitalia); Kapoor, 1968, Agra Univ. J. Res. (Sci.), 16(1) : 7.

**Figs. 276-280:** *Isolaboides burri* (Borelli), Male, 276. Dorsal view with (f. *macrolabic*) forceps; 277. Penultimate sternite with manubrium; 278. Ultimate tergite and (f. *microlabic*) forceps; 279. Genitalia; Female, 280. Ultimate tergite and forceps.

**Male:** General colour brownish black or black; head and pronotum shining; meso- and metanotum and abdomen dull with short and fine pubescence; legs with femora and tibia black, joints yellow and tarsi slightly lighter in colour.

Head smooth, slightly longer than broad, frons convex, sutures obsolete. Eyes shorter than post-ocular area. Antennae 13-segmented or more, 1st stout, shorter than the distance between antennal bases; 2nd short; 3rd long and cylindrical; 4th short, globular; 5th subconical, slightly longer than receding; 6th stout but equal to 3rd, remaining subconical and gradually increasing in length. Pronotum smooth, transverse, all margins straight, gently widened posteriorly, pro- and metazona little differentiated,
median sulcus faint. Meso- and metanotum strongly transverse, former with hind margin straight and in latter emarginate. Apterous. Legs short, femora thickened, hind tarsi with 1st segment about as long as the combined length of 2nd and 3rd; 2nd narrow, but longer than broad.

Abdomen weakly convex, gently dilated in posterior two thirds, sides of segments 5 to 9 obtuse angulate posteriorly. Penultimate sternite transverse, hind margin in middle convex, manubrium about as long as the sternite and of uniform width throughout. Pygidium vertical, not visible from above, triangular, base almost filling the space between the branches of forceps. Ultimate tergite weakly transverse, gently narrowed posteriorly, hind margin laterally above the bases of forceps oblique and in middle straight, sloping backwards, faintly depressed in middle posteriorly. Forceps stout, remote at base, branches straight and diverging up to a little beyond middle, afterwards abruptly and strongly bowed (f. macrolabia) or almost straight and gently incurved a little before apex (f. microlabia) with apices gently hooked, branches trigonal in basal one third. Genitalia with parameres longer than broad, narrowed apically, externally above forming an angle a little before apex, virga of left side spirally coiled but coils narrow and compact.

Female: Agrees with males in most characters except that ultimate tergite narrowed posteriorly and forceps simple and straight.

*Types*: 4 Males, 3 Females mentioned in the original description (Borelli, 1909) may be treated as syntypes; are perhaps preserved in MIZT.

*Distribution*: In the mountains of India (Kashmir) and Pakistan.

*Remarks*: This species can by easily determined by its strongly transverse pronotum; stout forceps, abruptly incurved in apical two thirds or gently incurved a little before apex; genitalia with parameres externally angular near apex and virga of left side with narrow loops and arranged in a compact linear fashion.

**Isolaboides immsi** (Burr)
(Figs. 281-288)

*Pseudisolabis burri* (néc Borelli); Burr, 1914, *Rec. Indian Mus.*, 10(5) : 290 (Female; India : Himachal Pradesh, Simla Hills, Matiana, 8000 ft.).

Isolaboides santokhi; Steinmann, *Dt. Ent. Z.*, 25 : 188.

Male : General colour brownish black, sides of pronotum, tarsi and antennae somewhat lighter in colour.

Head slightly longer than broad, smooth, frons weakly convex, sutures obsolete, hind margin emarginate in middle. Eyes generally black, sometimes whitish, about half as long or slightly less than post-ocular area. Antennae 15-segmented, 1st stout, shorter than the distance between antennal bases; 2nd short; 3rd long and cylindrical, gently expanded apically, slightly longer than 4th, remaining slightly increasing in length, one or two apical segments thin and rod shaped. Pronotum slightly broader than long, apical and lateral margins straight, gently widened posteriorly, hind angles rounded and margin almost straight or showing a trace of emargination in middle, smooth, impunctate; prozona weakly raised and scarcely differentiated from depressed metazona, median sulcus faintly marked on prozona. Meso- and metanotum transverse, obscurely reticulated, former with hind margin straight and latter broadly emarginate. Legs long and slender, hind tarsi with 1st segment about as long as the combined length of 2nd and 3rd; 2nd slightly longer than broad; 3rd about twice as long as 2nd; claw without an arolium. Abdomen spindle shaped, covered with very fine and short pubescence above, on sides a few long and short hairs present, sides of segments broadly convex. Penultimate sternite transverse slightly depressed posteriorly, hind margin subtruncate. Ultimate tergite transverse, smooth, sloping backwards with a roughly triangular depression in middle posteriorly, sides straight, hind margin in middle between the branches of forceps straight, oblique above the bases of forceps, gently narrowed posteriorly in microlabic form. Pygidium vertical, triangular. Forceps with branches remote at base in macrolabic form, strongly arcuate, internally differentiated into dorsal and ventral borders up to middle, afterwards branches circular in cross section, apices pointed and hooked; in forma microlabia comparatively less stout, straight in basal half; afterwards gently incurved. Genitalia with parameres broader at base, gradually narrowing apically to pointed apex, external and internal margin convex, distal lobe of left side enormously developed with spirally coiled virga, coils of virga loose and broad, distal lobe of right side atrophied.
**Female**: Agrees with males in most characters except that penultimate sternite obtuse posteriorly in middle; ultimate tergite narrowed posteriorly; pygidium vertical, narrow, posteriorly pointed and forcereps simple and straight.

**Measurements**: (in mm)

**Types**: Burr (1913) in the original description of *Pseudisolabis immsi* has mentioned “Male & Female” which may be treated as Types and are preserved in BMNH.

Holotype Male of *Pseudisolabis jonathani* Kapoor & Katiyar, 1971 at Division of Entomology, IARI, New Delhi.

Holotype Male of *Pseudisolabis santokhi* Kapoor & Katiyar, 1971, at Division of Entomology, IARI, New Delhi.

**Distribution**: India: Himachal Pradesh (Lahaul and Spiti, Chamba, Kinnaur and Kangra districts).

**Remarks**: This species can be separated from *I. burri* (Borelli), in *macrolabic* form, by its strongly curved and thin forcereps and genitalia with parameres narrowed apically, tip pointed and external and internal margin convex and virga with broad and loose spiral coils.

*Isolaboides rimosus* Steinmann

(Figs. 289-291)

**Male**: General colour dark reddish brown, legs lighter in colour. Head smooth, frons convex, sutures distinct. Eyes small, shorter than post-ocular area. Antennae 17‐segmented, 1st stout, shorter than the distance between antennal bases: 2nd short, quadrate; 3rd long and cylindrical, longer than 4th and 5th. Pronotum weakly transverse, parallel sided, angles rounded, median sulcus distinct. Apterous. Abdomen spindle shaped, finely punctulated, tergites convex. Penultimate sternite postero-laterally with an excised concavity, median lobe broad. Ultimate tergite transverse, posterior margin in middle lightly concave, oblique laterally above the bases of forcereps. Pygidium vertical, trigonal. Forcereps strongly incurved, trigonal in basal half, afterwards cylindrical, very similar to *I. burri*. Genitalia with parameres broad at base, narrowed apically, distal lobes indistinct, virga short and coiled.
**Type**: Holotype Male in MHNG.

**Distribution**: India: U.P. (Garhwal Hills).

**Remarks**: This species differs from all the known species of the genus by its characteristic penultimate sternite.

The male genitalia appears to represent the immature stage.

The coloured photograph of the penultimate sternite given by Sakai (1987, p. 2278) suggests that posterior concavities may not be natural but might be due to damage caused during pulling it off the specimen with forceps for the examination of genitalia.

In view of this, it seems necessary to examine the 'Type' for deciding the identity of the species.

**Uncertain species**

Isolaboides tenera (Burr)  
(Fig. 292)

**Male**: General colour dull brown with sparse pubescence.

Head slightly longer than broad, sutures obsolete. Eyes shorter than the post-ocular area. Antennae 17-segmented, 1st stout, shorter than the distance between antennal bases; 3rd long and cylindrical; 4th short, remaining increasing in length distally. Pronotum rectangular, gently widened posteriorly, sides and hind margin straight. Legs long and slender, hind tarsi with first segment equal to 2nd and 3rd together. Abdomen moderately convex, finely punctulated, contracted posteriorly. Penultimate sternite transverse, hind margin broadly rounded. Pygidium vertical, narrowed posteriorly. Ultimate tergite strongly transverse. Forceps remote at base, almost straight in most part except apices gently incurved.

**Female**: Not known.

**Measurements**: (in mm)

**Type**: Type (Holotype) Male in BMNH.

**Distribution**: Pakistan: Punjab, Murree.

**Remarks**: This species is so far known by its ‘Holotype Male’ but genitalia has not been described. In the original description “... second tarsal segment nearly as long as the first” has been mentioned, which is incorrect. It should be ‘first tarsal segment equal to 2<sup>nd</sup> and 3<sup>rd</sup> together’

It is almost certain that this species should be included under Isolaboides on the basis of external morphology.
**Isolaboides elegans** (Hebard)

(Figs. 293)

**Male**: General colour dull brown Finely pubescent.

Head with sutures marked by very feeble impressions. Eyes shorter than postocular area. Antennae with 1st segment stout, shorter than the distance between antennal bases. Pronotum rectangular, widened posteriorly, sides and hind margin straight. Legs long and slender, hind tarsi with first segment almost equal to second and third together; second more than half as long as the third. Abdomen moderately convex, sides of abdominal segments broadly convex posteriorly. Penultimate sternite, transverse, hind margin rounded with slight emargination in middle. Ultimate tergite strongly transverse. Pygidium declivent; trigonal with apex rounded. Forceps with branches remote at base, regularly and strongly incurved, tapering apically with tips strongly hooked, cylindrical but in middle inner surface flattened.

Female : Agrees with males in most characters except that penultimate sternite with hind margin comparatively not so broadly rounded and forceps simple and straight, trigonal above.

**Measurements** : (in mm)

**Types**: Type (may be treated as the Holotype) Male, Allotype female, Paratypes 1 Male and 2 Females at MCZH.

**Distribution**: India: Himachal Pradesh, Kulu Kangra.

**Remarks**: On the basis of external morphology it appears to be conspecific with *Isolaboides immsi* (Burr). However, its true identity can be established when the male genitalia is described.

**Family** **LABIDURIDAE**

Size medium to large (7.0 – 26.0 mm). Body generally not depressed, stout. Elytra and wings well developed except in the members of Gonolabidura Zacher, sometimes former abbreviated and latter absent. Male genitalia with two functional lobes, parameres with a large or small epimerite, sometime absent, virga stout, tubular, at base sometimes with a vesicle or only a dilation and inside the virga with a sinuous tube throughout the length or at base only.

Distribution: World wide.

Family ALLOSTETHINAE

Size medium to large (12.0 – 32.0 mm in length); colour generally dark reddish brown to black; stout, abdomen moderately convex. Prosternum narrowed posteriorly to a sharp point. Male genitalia with proparameres paired, distal lobes with tubular and stout virga, at base occasionally dilated, parameres acute apically.

Type genus: Allostethus Verhoeff, 1904 (Designated by Burr, 1909, Dt. ent. Z., 1909: 324).

Distribution: Oriental Region.

Remarks: This subfamily is mainly characterised by the strongly narrowed prosternum posteriorly into a sharp point.

Three genera are included under the subfamily, of which only two viz., Allostethus Verhoeff, 1904 and Gonolabidura Zacher, 1910 are represented in India.

Key to genera

1(2). Elytra and wings present, occasionally latter absent; pronotum quadrate or weakly transverse; virga almost straight ......................... Allostethus Verhoeff
2(1). Apterous; pronotum distinctly transverse; virga dilated in basal half, with double curves and dilated in basal half.................... . .

**Gonolabidura** Zacher

**Genus Allostethus** Verhoeff

Build stout; size large (25.0 – 30.0 mm). Antennae multi-segmented, basal segment, from 2 to 5 broader, hardly narrowing at base; 3rd segment slightly longer than broad; 4th and 5th almost quadrate. Elytra well developed, smooth and wings occasionally absent. Pro- and mesosternum strongly narrowed posteriorly. Abdomen long, cylindrical, tergites convex. Male genitalia with virga narrow and tubular with a darker stripe on one side.

**Type species**: *Forficula indica* Burmeister, 1838 (Designated by Burr, 1909, *Dt. ent. Z.*, 1909: 324).

**Distribution**: Oriental Region.

**Remarks**: Out of 12 known species only one species is recorded from South India.

*Allostethus anamalayanus* Ramamurthi

(Figs. 294-299)

**Male**: General colour blackish brown, bluish sheen on head pronotum and elytra; antennae and legs brown and forceps dark reddish brown.

Build stout. Head longer than broad, frons convex, sutures fairly marked, hind margin emarginate in middle. Eyes prominent but shorter than post-ocular area. Antennae 23- (+ more) segmented, 1st segment shorter than the distance between antennal bases; 2nd short, about as long as broad; 3rd long, slender, three times longer than broad; 4th stout, globular; 5th slightly longer than 3rd, narrowed basally, afterwards segments gradually thinning and each one narrowed basally, apical ones thin and rod shaped. Pronotum transverse, gently widened posteriorly, lateral margin depressed, almost straight, hind margin subtruncated, median sulcus distinct; prozona tumid indistinctly separated from weakly depressed metazona.
Elytra slightly longer than pronotum, hind margin obliquely truncate, axillary angle rounded off to show transverse scutellum. Legs clear yellow, hind tarsi with 1st and 3rd segment equal, claw without an arolium. Abdomen long, cylindrical, widened posteriorly, tergites convex, with an oval smooth patch above laterally, basal three tergites impunctate, afterwards punctuation with microreticulation, gradually becoming heavier in posterior tergites, sides of segments convex posteriorly, rugosely punctate. Penultimate sternite transverse, narrowed posteriorly, hind margin rounded with slight emargination in middle. Ultimate tergite transverse, disc convex, sloping backwards, in anterior half sparsely and in posterior half densely punctate, a feeble lateral carina present running almost the entire length of tergite and turning obliquely inwards near posterior margin, hind margin between bases forceps almost straight and slightly raised, laterally obliquely sinuate. Forceps subcontiguous and broad at base, tapering apically, trigonal with ridge extending up to the middle of the length or more, right branch almost straight in basal 2/3, left branch almost straight in basal 1/2, afterwards strongly incurved, and crossing over right branch, apices
hooked and pointed, inner margin of right branch with a small sinuature and with one or two teeth near base, otherwise unarmed, left branch with a strong triangular tooth near base followed by several small teeth all along the length. Genitalia with parameres narrow, about five to six times longer than abroad, narrowed apically with tip pointed, oblique membrane present; distal lobes with virga tubular.

**Female**: Agrees with males in most characters except that penultimate sternite posteriorly, in middle, obtuse; ultimate tergite comparatively narrower and forceps simple and straight.

**Measurements** : (in mm)

**Types**: Holotype male, Allotype female with the author; Paratype 1 Male in MM.

**Distribution**: So far only known from the type locality, i.e., India: Tamil Nadu, Anamalai Hills, Cinchona, 3500 ft.

**Remarks**: This species is confined to Western Ghats. In the collections of Z.S.I. several specimens from the type locality are present which include males, females and nymphs. Except for the slight variation in body colour no other morphological variation could be observed.

**Genus** *Gonolabidura* Zacher

Totally apterous; head longer than broad; antennae multi-segmented, 1st slightly shorter that the distance between antennal bases and pronotum distinctly transverse. Male genitalia with parameres long, narrow, pointed apically, distal lobes with virga dilated at base, usually with double bend, otherwise unarmed.

**Type species**: *Anisolabis piligera* Bormans, 1900 (= *Gonolabidura voltzi* Zacher, 1910).

**Distribution**: Oriental Region.
Key to species (based on Males only)

1(4). Size larger, usually above 15 mm; sides of abdominal segments convex

2(3). Body colour shining black; ultimate tergite without lateral carina and forceps elongated, and straight.................................G. biswasi Srivastava

3(2). Body colour shining brownish or reddish black; ultimate tergite with distinct lateral carina and forceps strongly arcuate .......................G. astruci Burr

4(1). Size smaller, usually below 15 mm; sides of abdominal segments obtuse or acute

5(6). Size smaller, up to 11.5 mm or less; abdominal tergites shallowly and sparsely punctulate and ultimate tergite with lateral carina represented by a faint linear convexity and forceps elongated.................................G. minor Burr

6(5). Size larger, above 12.5 mm; abdominal tergites heavily punctate; ultimate tergite with a prominent carina laterally and forceps stout and incurved ...

.................................................................G. nathani Brindle

Gonolabidura astruci

Build stout, body strongly pubescent. General colour shining, blackish brown, antennae with basal segment lighter in colour; legs yellowish brown.

Head longer than broad, smooth, sutures faint, frons convex, hind margin in middle faintly emarginate. Antennae 17-segmented (+ more), basal segment stout, narrower at base, shorter than the distance between antennal bases; 2nd short, about as long as broad; 3rd slender, a little over twice longer than broad; 4th a little stouter and shorter than preceding; 5th about as long as 3rd, narrowed basally, remaining gradually increasing in length, thinning and each narrowed basally. Eyes prominent but shorter than post-ocular area. Pronotum rectangular, slightly broader than long, smooth, impunctate, median sulcus obsolete, all margins straight, sides feebly reflexed, prozona weakly raised and metazona weakly depressed. Meso- and metanotum with same texture as the pronotum, former about as long as pronotum with hind margin truncate and latter strongly transverse, broadly concave posteriorly. Legs stout, hind tarsi
with 1st segment stout, equal to third, clad with hairs on underside, claw without an arolium. Abdomen broad, narrowed at base, gradually dilating up to 9th tergite, tergites convex, obscurely punctulate, sides of segments 6th to 9th convex, rugosely punctate. Penultimate sternite transverse, punctulate, narrowed apically with hind margin in middle truncate, pubescent, in posterior half with thick yellow long hairs. Ultimate tergite transverse, weakly raised, sloping backwards, punctulate, median sulcus distinct, laterally with a distinct ridge, hind margin slightly concave in middle and above bases of forceps oblique and concave. Pygidium vertical, narrowed posteriorly. Forceps at base remote, stout, strongly arcuate, trigonal at base above, inner margin finely serrated. Genitalia with parameres, a little over five times longer than broad, narrowed apically with tip acute; distal lobe with virga, stout dilated at base.

Female: Agrees with males in most characters except that penultimate sternite obtuse in middle posteriorly; ultimate tergite narrower with a faint linear convexity laterally and forceps simple, straight, inner margin dentate in basal half.

Nymphs: Similar to adult but smaller in size, lighter in colour, antennae with annular yellow ring at base on each segments.

*Types :* Syntype Male and Females in BMNH.

*Distribution :* India : Tamil Nadu : Shembaganur and Upper Manalaar, alt 1500 m, ca 50 Km W of Madurai; 8 m in NE of Munnar, 6200 ft.

*Remarks :* In the collection of the Zoological Survey of India, Calcutta this species is represented by 4 Males, 1 Female and 7 nymphs from India : Tamil Nadu : Upper Malanaar, alt. 1500 m, High Wavy Mts., ca 50 km W of Madurai, 15.2.1986, Coll. S.S.Saha hitherto not reported.

This species comes closer to *G. nathani* Brindle, but differs in Males, by having thick pubescence in posterior half of penultimate sternite; strongly incurved forceps and larger body size.

*Gonolabidura minor* Burr

(Figs 304 – 307)

Build moderate; general colour shining reddish brown with traces of black on certain abdominal segments laterally, antennae with basal two segments and one or two ante-apical ones clear yellowish brown. A few long and short hairs present.

Head about as long as broad, impunctate, scarcely emarginate in middle posteriorly, frons convex, sutures fine. Eyes distinct, but shorter than post-ocular area. Antennae 15-segmented, 1st stout, gently expanded apically, shorter than the distance between antennal bases; 2nd short about as long as broad; 3rd long, slender; 4th stout but shorter than preceding; 5th about as long as 3rd but narrowed basally; 6th onwards gradually thinning and increasing in length distally, a few apical ones thin, rod shaped. Pronotum quadrate, slightly broader than long, impunctate, all margins straight, sides gently reflexed in middle, median sulcus faint, prozona raised, distinguished from weakly depressed metazona. Meso- and metanotum of same texture as pronotum, former about as long as pronotum with hind margin subtruncate and latter transverse with hind margin broadly emarginate. Abdomen long, gradually enlarging posteriorly,

tergites convex, sparsely and shallowly punctuated, sides of segments 7-9 acute angled posteriorly, shallowly punctulate. Penultimate sternite transverse, narrowed posteriorly with hind margin scarcely emarginate in middle, obscurely punctulated. Ultimate tergite transverse, disc flat, shallowly and sparsely punctulate, median sulcus absent, laterally above with a faint convex line merging with hind margin, above ridge of forceps, laterally sloping, hind margin scarcely sinuate in middle above bases of forceps, concave and oblique. Forceps broad, subcontiguous at base, tapering apically, in apical one third incurved, apices hooked and pointed, trigonal in basal 1/3, afterwards depressed, inner margin finely serrated. Genitalia with parameres about four times longer than broad, narrowed apically, tip acute; virga tubular dilated at base, narrowed apically, bent in apical 1/3.

Female: Agrees with males in most characters except ultimate tergite lacking lateral linear convexity and forceps simple and straight.

**Types**: Male and nymph in BMNH.

Burr (1914) based the original description on one Male and nymph. Former may be treated as the 'Type' although not so designated.

**Distribution**: India: Tamil Nadu: Anamalai Hills, 4000 ft., Cinchona 3500 ft.

**Remarks**: Brindle (1965) records both the sexes but body measurements are not given separately.

**Gonolabidura nathani** Brindle

(Figs. 308–311)

General colour shining blackish brown or reddish black; head posteriorly, antennae with basal segment light brown; legs yellowish brown. Pubescent, more pronounced on the sides of abdominal segments.

**Male**: Head about as long as broad, smooth and impunctate, feebly emarginate in middle, frons tumid, sutures fine but distinct. Eyes prominent, shorter than postocular area. Antennae 15-segmented; 1st segment stout, narrowed at base, shorter than the distance between antennal bases; 2nd short, about as long as broad; 3rd long, slender, a little over one and half times longer than broad; 4th stout, slightly longer than broad; 5th about as long as the 3rd; 6th onwards segments gradually increasing in length and each narrowed basally, a few apical one thin. Pronotum smooth, transverse, all margins straight, median sulcus distinct, prozona weakly raised, poorly differentiated from weakly depressed metazona. Mesonotum transverse, only slightly shorter than pronotum in length and of same texture, hind margin truncate. Metanotum smooth, transverse, hind margin broadly emarginate. Legs typical of the genus. Abdomen slightly enlarged posteriorly, tergites convex above, punctate, sides of segment 7th to 9th acute angled posteriorly and rugosely punctate. Penultimate sternite transverse, punctulated, narrowed posteriorly, hind margin in middle subtruncate. Ultimate tergite transverse, disc moderately raised in middle, sloping backwards and feebly depressed in middle, median sulcus deep and distinct in middle, hind margin scarcely emarginate, above base of forceps oblique and emarginate, laterally with a sharp ridge in apical 2/3. Forceps with branches subremote and stout near base, attenuated backward, almost straight in basal 2/3, afterwards incurved, apices gently hooked, trigonal above in basal 1/3, afterwards...
Figs. 308 - 311: *Gonolabidura nathani* Brindle, Male; 308. Dorsal view; 309. Hind portion of penultimate sternite; 310. Genitalia; Female; 311. Ultimate tergite and forceps.

Depressed, inner margin finely serrated. Genitalia with parameres long, narrowed apically, tip acute, membrane distinct; virga dilated at base, with double bend, accessory chitinuous structures present.

Female: Agrees with male in most characters except that penultimate sternite obtuse in middle posteriorly; ultimate tergite narrowed posteriorly, laterally with a faint linear convexity and forceps simple, straight, inner margin strongly dentate.

*Types*: Brindle (1965) has not stated the repository of Holotype Male. Perhaps it may be either in MM or BMNH.
**Distribution**: India: Coimbatore dist., Anamalai Hills, Valparai 3500 ft and Cinchona, 3500 ft.

**Remarks**: This species agrees with *Gonolabidura minor* Burr, in most details except that it differs in being slightly larger in size, more pubescent and, in males, the ultimate tergite is comparatively heavily punctate, median sulcus distinct and with a sharp lateral carina. Although *G. minor* and *G. nathani* are considered as distinct species on the basis of available information and specimens, it would be desirable to examine the population of both the species to establish the validity of above distinguishing characters.

**Gonolabidura biswasi** Srivastava
(Figs 312–319)

(Holotype Male and Paratype 1 Female; India : Arunachal Pradesh : Tirap dist., Gandhigram, ca 35 km from Miao).

**Male**: General colour shining black, mouth parts, knee joints and tarsi brownish. Head slightly longer than broad, smooth, impunctate, frons convex, sutures fine, hind margin emarginate. Eyes small, about half as long as the post-ocular area. Antennae partly damaged, only 9 basal segments on the right side remaining, 1st stout, narrowed basally, slightly shorter than the distance between antennal bases; 2nd short, about as long as broad; 3rd segment three times longer than broad; 4th about as long as broad; 5th longer than broad and slightly shorter than 3rd; 6th onwards segments gradually increasing in length and comparatively less stout. Pronotum transverse, smooth, anterior margin lightly convex, sides and hind margin straight, former gently reflexed; prozona weakly raised and not well differentiated from flat metazona, median sulcus faint. Meso- and metanotum transverse, former with hind margin straight and latter with hind margin broadly emarginate. Sternal plates typical, mesosternum prolonged posteriorly into a narrow process. Legs stout, hind tarsi with 1st and 3rd segments equal in length and 2nd short. Abdomen narrowed at base, enlarged in middle, long and short pubescence present on sides, tergites weakly convex, obscurely punctuated, sides of segments convex, rugosely striate. Penultimate sternite clad with long pubescence, roughly triangular, hind margin in middle posteriorly truncate, manubrium about 1/3 as long as the sternite. Ultimate tergite transverse, gently narrowed posteriorly, hind margin in middle straight, laterally oblique and emarginate, disc weakly depressed, median sulcus faint. Forceps subcontiguous, broader at base, tapering apically, almost straight, gently incurved in apical 1/3, tip hooked and pointed, trigonal above in basal 1/3, afterwards depressed, internal margin dentate. Genitalia as seen in fig. 318.

**Female**: Agrees with male in most characters except that ultimate tergite weakly transverse, penultimate sternite obtusely rounded posteriorly and forceps simple and straight.

**Types**: Holotype Male and Paratype Female in ZSI.

**Distribution**: India: Arunachal Pradesh: Changlong dist. (earlier Tirap dist.), Gandhigram, ca 35 km from Miao.

**Remarks**: The genus *Gonolabidura* is represented, in India, by three species confined to Western Ghats. This is the only species which is at present known to occur in North Eastern India.

It is quite distinct from other Indian species by its large size and other morphological details.
Subfamily NALINAE

Nalinae Steinmann, 1975, Acta zool. hung., 21 : 207 (Type genus: Nala Zacher, 1910);

Size small to medium, below 15 mm. Elytra with a ridge along the costal margin. Legs comparatively short, hind leg with femora or tarsi not longer than pronotum, hind tarsi with first and third segment subequal in length. Male genitalia with parameres narrowed apically and without an obvious epimerite.

Type genus: Nala Zacher, 1910.

Distribution: Ethiopian, Oriental, Paleartic (South Europe) and Australian Regions.

Nala Zacher

Paralabidura Burr, 1910, Trans. ent. Soc. Lond., 1910 : 184 (Type species: Forficula lividipes Dufour, 1829, by original designation); Burr, 1911, Genera Insect., 122 : 35 (treated as synonym of Nala Zacher, 1910).

Size medium to small (15 mm or less). Head convex, transverse; antennae 20-segmented or more; eyes shorter than the post-ocular area. Pronotum longer than broad or transverse, hind margin briefly or strongly rounded. Elytra and wings well developed, former with a ridge laterally and latter rarely abbreviated. Legs short. Abdomen convex, dilated in middle, smooth. Forceps, in male, stout, incurved, sometimes dilated in basal half, internally armed. Genitalia with parameres narrowed apically, without an epimerite.

Type species: Forficula lividipes Dufour, 1829.

Distribution: African and Oriental except for Nala lividipe which is extensively distributed throughout the world.
In the Indian region only three species are known of which two namely, *N. basalis* Bey-Bienko and *N. nepalensis* (Burr) are distributed in the mountains of Oriental Region whereas *N. lividipes* (Dufour) has worldwide distribution, more common in warmer parts.

**Key to the species (on males only)**

1(2). Forceps in basal 1/3 to 1/2 dilated internally .................. *N. nepalensis* (Burr)
2(1). Forceps long and cylindrical, not dilated internally

3(4). Penultimate sternite with hind margin in middle rounded; forceps armed internally at middle with one or two teeth, sometimes absent, parameres acute apically ........................................... *N. lividipes* (Dufour)
4(3). Penultimate sternite with hind margin in middle obtusely produced; forceps at base with or without a short depressed tooth internally, afterwards branches finely serrated; parameres acuminate apically .......... ...................................................... *N. basalis* Bey-Bienko

**Nala lividipes** (Dufour)

(Figs. 320-325)

*Forficula pallipes* Dufour, 1820, *Ann. gener des Sc. Phys. de Bruxelles*, 4: 316, pl. 116, figs. 7, 7a & 7b (Male, Female; Lower Catalonia, Spain—Location of Type unknown).

Figs. 320-325: *Nala lividipes* (Dufour), Male; 320. Anterior portion of body; 321. Hind portion of penultimate sternite; 322-323. Ultimate tergite and forceps; 324. Genitalia; Female; 325. Ultimate tergite and forceps.

Forficula dufouri Desmarest, 1820, Fauna fr. Orth., pl. 1, fig. 7.

Forficesila vicina Lucas, 1846, Expl. Alger, 3 : 5, pl. 1, fig. 2, 2a.

Labidura lividipes vicina Bormans, 1900, Das Tierreich, 11: 36.

Labidura inconspicua Kirby, in Distant, 1900, Ins. Transvaal., 1 : 12, pl. 1, fig. 1.

Echinosoma? obscurum Kirby in Distant, 1900, Ins. Transvaal., 1 : 12, pl. 1, fig. 2.

Labidura australica Mjoberg, 1913, Ent. Tidsskr, 1913 : 27.

Male : General colour dull blackish brown, with varying intensity; mouth parts, sides of pronotum and leg joints dirty yellow; a few pre-apical antennal segments yellow.

Head convex, smooth, hind margin emarginate in middle. Eyes shorter than postocular area. Antennae 20-segmented, basal segment about as long as the distance between bases of antennae; 2nd short, about as long as broad; 3rd long, slender, slightly longer than 4th to 6th; 4th slightly shorter than 5th, both stouter than preceding; 7th almost equal to 3rd in length, remaining gradually increasing in length and thinning. Pronotum longer than broad, gently widened posteriorly with margin rounded, prozona tumid and metazona depressed. Elytra and wings well developed, former with a carina at costal margin. Abdomen finely pubescent, gradually enlarging posteriorly. Penultimate sternite triangular, emarginate in middle posteriorly. Ultimate tergite transverse, tumid above the roots of forceps, depressed inbetween. Forceps with branches stout, gently incurved, tapering, apices pointed, inner margin ventrally crenulate with a distinct tooth at apical third, often obsolete. Genitalia with parameres a little over three times longer than broad, narrowed apically, tip acute, external margin convex; virga thin, tubular, basal vesicle distinct.

Female : Agrees with males in most characters except ultimate tergite strongly narrowed posteriorly; forceps simple and straight, crenulate internally in basal half.

Types: Type Male, Female of *Forficula pallipes* Dufour, 1820 – repository unknown; Type locality Lower Catalonia, Spain.

Type Male of *Forficula dufori* Desmarest, 1820 – repository unknown; type locality also not known.

Type Male of *Forficesila castanea* Serville, 1839 – repository unknown; Type locality – Spain.

Type Male of *Forficesila meridionalis* Serville, 1839 – repository unknown; Type locality – Andalusia.

Type Male, Female of *Forficesila vicina* Lucas, 1846 – Type Male – repository unknown; Type locality – Algeria.

Type Female of *Labidura inconspicua* Kirby: in Distant, 1900, - repository unknown; Type locality – Transvaal, Pretoria.

Type Female of *Echinosoma(?) obscurum* Kirby: in Distant, 1900 – repository unknown; Type locality – Transvaal, Pretoria.

Type Male of *Labidura australica* Mjöberg, 1913, - repository unknown; Type locality – West Kimberly, N.S.W. Australia.

In the collection of the Zoological Survey of India, Calcutta it is represented from India: W.B., Orissa, Rajasthan, U.P., Jammu & Kashmir, Tamil Nadu, Karnataka; Nepal and Sri Lanka.

Remarks: Body colour ranges from blackish brown to testaceous brown; inner tooth of male forceps often obsolete.

This species is quite common in Calcutta during rainy season and attracted to light in large numbers.

*Nala nepalensis* (Burr)

(Figs. 326-329)

Figs. 326-329: *Nala nepalensis* (Burr), Male; 326. Dorsal view; 327. Hind portion of penultimate sternite; 328. Genitalia; Female; 329. Ultimate tergite and forceps.

Male: General colour brownish black; antennae testaceous, legs yellow with femora and tibiae blackish in basal half; ultimate tergite, forceps reddish, shaded with black. Finely pubescent.

Head smooth, convex, about as long as broad, sutures obsolete. Eyes smaller than post ocular area. Antennae 22-segmented, basal segment stout, almost equal or slightly shorter than the distance between bases of antennae, expanded apically; 2nd short, about as long as broad; 3rd long, slender; 4th slightly longer than abroad, succeeding segments gradually increasing in length; 4th and 5th shorter than 3rd; and 6th equal to 3rd. Pronotum about as long as broad, rugose, sides straight, a little reflexed, hind margin rounded. Elytra ample, rugose, tuberculated, keeled along the costal margin, hind margin straight. Wings well developed, of same texture as elytra. Legs normal. Abdomen finely pubescent, parallel sided or gently dilated in middle, finely punctate, lateral tubercles not visible. Penultimate sternite obtuse angular posteriorly, hind margin truncate and gently emarginate in middle posteriorly. Ultimate tergite transverse, sometimes tumid above the roots of forceps, hind margin sinuate in middle. Pygidium scarcely visible from above, rounded posteriorly. Forceps with branches stout, internally dilated in basal 1/3 with its inner margin serrated and a small tooth posteriorly, afterwards branches cylindrical, gently incurved, narrowed apically, tip pointed. Genitalia with parameres about five times longer than broad, narrowed apically, tip acute; virga thin and tubular.

Female: As male but differs in having ultimate tergite narrowed posteriorly; forceps simple, straight with apices gently incurved, meeting, inner margin irregularly denticate.

Types: Burr (1907a) listed altogether 4 males and 6 females from Nepal but none of them was designated as the Type. He (1910) mentions "Type in the Indian Museum" The collections belonging to Indian Museum is now present in the Zoological Survey of India, Calcutta.

Out of the above specimens 1 Male labelled as "Nepal, Sondrijal, Reg. No. 1285/15" bears a handwritten label, probably by Burr, "Labidura nepalensis Burr Type" may be treated as the Holotype. Besides five more specimens bearing Reg. Nos. 1245/15, 1283/15, 1284/15, 1286/15 and 1299/15 are present which may be considered as
Paratypes. The specimens with Reg. No. 1286/15 is a Male and 1299/15 is a Female. It is not possible to determine the sex of remaining three specimens since hind portion of body is missing.

**Distribution:** India: Arunachal Pradesh, Assam, Meghalaya, Manipur, Tripura, Mizoram, Nagaland, West Bengal (Darjeeling dist.), Sikkim, Uttar Pradesh (Hill dists.), Himachal Pradesh, Punjab and Jammu and Kashmir.

Also reported from West Pakistan, China, Nepal, Bhutan and Malaya.

**Remarks:** It is mainly mountain dwelling species occurring under stones on the edge of water bodies, rivers and streams.

General body colour varies from dull brownish black to shining reddish.

**Nala basalis** Bey-Bienko

(Figs. 330-335)

Male: Head, antennae, pronotum, elytra and wings dark brownish black; mouth parts, sides of pronotum and legs yellowish, but femora and tibiae brownish black in basal half only, abdominal tergites somewhat lighter, ultimate tergites and forceps reddish brown. Antennae, head, abdomen and forceps thickly pubescent; pronotum, elytra and wings pilose except for a few small hairs on margins only.

Head slightly longer than broad, convex above, sutures obliterated, hind margin almost straight. Antennae 23-segmented or more, 1st stout, gently expanded apically, about as long as the combined length of 2nd and 3rd; 2nd small, about as long as broad; 3rd long, cylindrical, longer than all the succeeding segments up to 19th and equal in length to 20th; 4th onwards segments gradually increasing in length and each segment gently expanded apically, and becoming thinner distally. Eyes distinct but shorter than post-ocular area. Pronotum slightly longer than broad, widened posteriorly with hind margin and angles broadly rounded, median suture distinct; prozona raised and well differentiated from flat metazona. Elytra and wings well developed, shining, former with a distinct ridge along the costal margin, above faintly roughened. Legs normal. Abdomen densely punctulate, convex, parallel sided, lateral tubercles on 3rd and 4th tergites poorly marked. Penultimate sternite punctulate, triangular, sides scarcely concave, hind margin obtusely produced in middle. Ultimate tergite transverse, convex above, slightly depressed in middle, oblique laterally, hind margin posteriorly, in middle, sinuate. Pygidium scarcely visible from above, vertical, narrowed apically with margin rounded. Forceps with branches remote, gradually incurved in basal 1/3, afterwards straight and tapering to pointed and gently hooked apex, trigonal.
above in basal one fifth, afterwards weakly depressed, internally at base with a depressed lobe, directed backwards with its inner margin serrated; in one male basal lobe is slightly larger but narrow; beyond basal lamellation branches internally serrated. Genitalia with parameres a little over five times longer than broad, narrowed apically, tip acuminate; virga distinct, tubular.

Female: Agrees with males in most characters except that ultimate tergite narrowed posteriorly and forceps with branches simple and straight.

**Types** : Holotype Male, Paratypes 2 Females in ZSM and Paratypes 7 Females HNAB.

**Distribution** : East Afghanistan, Pakistan, India (Manipur and Mizoram). Also reported from Thailand.
**Remarks**: This species comes very close to *Nala nepalensis* Burr, but differs by the shape of penultimate sternite in being broadly obtuse in middle posteriorly (vs fanitly emarginate in middle posteriorly in *N. nepalensis*); pygidium convex only (vs bifid or obtuse apically); forceps at base internally with a narrow backwardly pointed lobe, often slightly larger but extending in basal one fifth (vs internally dilated upto basal half with its inner margin contiguous and strongly serrated); and parameres apically acuminate (vs tip narrowed with apex acute).

Following specimens preserved in the Z.S.I. are reported for the first time:

India: Manipur, 3 km Moreah West, alt. 2000 ft., 2 Males, under stones on river bank, 25.10.1975 (*M. S. Shishodia* Col.); Mizoram, Chhimtuipui dist., Tapui river (bank), 1000 ft., 2 Males, 2 Females, 23.3.1979 (*P.T.Cherian* Col.).

**Subfamily LABIDURINAE**

Size large, generally more than 15 mm in length. Elytra along the costal margin ecarinate, occasionally a faint convexity present. Legs long, hind femora longer than the pronotum.

*Type genus*: *Labidura* Leach, 1815.

*Distribution*: Worldwide.

**Key to genera**

1(2). Sides of abdominal segments in males without spines; forceps robust, evenly curved; parameres with a short epimerite apically ........... *Labidura* Leach

2(1). Sides of certain abdominal segments in normal males with spines or tubercles; forceps generally elongated, demarcated into basal curved, remote part extending up to or beyond middle, afterwards contiguous or subcontiguous and straight; parameres apically with a comparatively longer epimerite ......

.............................................................................. *Forcipula* Bolivar
Genus **Labidura** Leach

Size medium to large (12.0–24.0 mm), rather depressed. Head convex, eyes prominent but always shorter than post ocular length; antennae 20-35 segmented, 1st equal to 3rd. Elytra and wings well developed, former keeled laterally and latter sometimes abbreviated. Abdomen without spines or crests on sides of segments; forceps, in male, stout, remote at base, slender, gently arcuate, variously armed internally.

**Distribution**: Worldwide.

**Remarks**: Only two species are known from the area, of which the status of *Labidura dharchulensis* Gangola, is doubtful. For this reason a key for the separation of species is not given.

*Labidura riparia* (Pallas)

(Figs. 336-339)

*Forficula riparia* Pallas, 1773, *Reise Russ, Reichs*, 2 : 727 (Sex ?; Shores of Irtyshch River, Western Siberia).

Forficula maxima Villiers, 1780, *Linn. Ent.*, 1 : 427 (Type Male; Europe).

Forficula gigantea Fabricius, 1787, *Mant. Ins.*, 1 : 224 (Male; Europe).

Forficula bidens Olivier, 1791, *Encyl. Méthod.*, 3 : 466 (Male; South America).

Forficula crenata Olivier, 1791, *Encyl. Méthod.*, 3 : 467 (Female; Central Africa).

Forficula flavipes Fabricius, 1793, *Ent. Syst.* 2 : 2 (Female; Guinea).

Forficula erythrocephala Fabricius, 1793, *Ent. Syst.*, 2 : 4 (Male; West Indies).

Forficula affinis Guérin-Méneville, in Ramon, 1836, *Hist. Cuba Ins.*, 7 : 330, pl. 12, fig. 2 (Male; Cuba).

Forficesila gigantea Burmeister, 1838, *Hand. Ent.*, 2 : 751 (Female; Antillen).

Forficula suturalis Burmeister, 1838, *Hand. Ent.*, 2 : 752 (Male; Colombia).

Labidura granulosa Kirby, 1891, *J. Linn. Soc. Zool.*, 23 : 511 (Female; Philippines).

Labidura clarki Kirby, 1891, *J. Linn. Soc. Zool.*, 23 : 512 (Female; Brazil).

Labidura distincta Rodzianko, 1897, *Wein ent. Ztg.*, 16 : 153 (Male; Europe Occ.).

Labidura riparia hurculeana Semenov, 1908, *Ent. Obozr.*, 1908: 171 (Male; South Russia).

Labidura leucotarsata Mjöberg, 1913, *Ent. Tidskr.*, 34: 27 (Male; West Australia).

Labidura cryptera Liu, 1946, *J. West China Border Res. Soc.*, 16: 20, fig. 6 (Male, Female; China: Chunking) - Syn. n.

Male: General colour varies from yellowish brown to dark blackish brown with various intermediate shades. Antennae, legs and wings generally testaceous.

Head transverse, convex, sutures faint or distinct; eyes prominent but shorter than post-ocular area. Antennae 25-36 segmented, first or basal segment stout, shorter than the distance between antennal bases; 2nd about as long as broad; 3rd long, slender, a little over twice as long as broad; 4th and 5th shorter than 3rd, afterwards segments gradually thinning and increasing in length. Pronotum slightly longer than broad, sides straight or often convex, posteriorly rounded; prozona raised and metazona depressed. Legs with femora inflated, fore leg and middle leg with basal and apical segment of tarsi equal in length but hind tarsi with basal segment longer than apical segment. Elytra well developed or reduced in length, upper surface rugose, a faint ridge along the costal margin. Wing generally present, occasionally reduced or concealed below elytra, rugose above. Abdomen weakly depressed, punctulate, gradually enlarging posteriorly. Penultimate sternite obtusely triangular, hardly emarginate in middle posteriorly. Ultimate tergite transverse, smooth, disc convex, two sharp spines at posterior margin present or sometimes obsolete, with a triangular depression in middle posteriorly, tumid above root of forceps. Forceps remote at base, trigonal above for a short distance, long, cylindrical, tapering apically, internally toothed but
their position extremely variable. Genitalia with parameres flat, three to four times longer than broad, sides straight, sometimes slightly narrowed basally, apically a membranous epimerite present; virga basally with a vesicle, and inner sinuous tube.

Female: Agrees with male in most characters but slightly smaller in size; abdomen dilated in middle; ultimate tergite narrowed posteriorly; forceps simple, straight and contiguous throughout.

*Measurements*: (in mm)

Type Male of *Tomopyga sinensis* Burr, 1904 in MNHP.
Type and type locality of *Labidura dubronyi* Börg, 1904 – unknown.
Type and type locality of *Labidura karschi* Börg, 1904 – unknown.
Type Male of *Labidura mongolica* Rehn, 1906 in USNM.
Type Male of *Labidura riparia harculeana* Semenov, 1908 – repository not known.
Type Male of *Labidura leucotarsata* Mjöberg, 1913 in NRSS.
Type Male of *Labidura coufusa* Capra, 1929 in MSNG.
Type Male, Female (actually nymphs) of *Labidura cryptera* Liu, 1946 – repository not known; in the original description number of specimens not mentioned – in MZSC.
Type Male (actually nymph) of *Labidura elegans* Liu, 1946 – repository not known; in the original description only male is mentioned – in MZSC.
Type nymphs of *Diplatys himalayanus* Baijal and Singh, 1954 – in ZSI.
Type Male of *Spongiphora nainitalensis* Baijal and Singh, 1954 – in ZSI.
Type Female of *Erotesis jeolikotensis* Baijal and Singh, 1954 – in ZSI.
Type Male of *Elaunon nainitalensis* Baijal and Singh, 1954 – in ZSI.
Holotype Male of *Labidura orientalis* Steinmann, 1979 – in HANB.

*Distribution*: Worldwide.

In the Indian subcontinent this species has been recorded from sea shore to mountains under diverse habitats but is more common in tropical parts.

*Remarks*: This is an extremely variable species in general body colouration, size, shape of pronotum, texture and extent of elytra and wings, ultimate tergite and forceps, especially inner armature.

All these variations have been described in detail by Burr (1910) and Habard (1923).

Srivastava (1986) has rightly treated four species viz., *Diplatys himalayanus*; *Spongiphora nainitalensis*; *Erotesis Joelikotensis* and *Elaunon nainitalensis* described by Baijal and Singh (1954) as synonyms since these are based on individual variants of this species.

*Labidura cryptera* and *Labidura ? elegans* Liu (1946) are based on nymphs which is confirmed by the figures. There appears to be no difference in morphological details and are treated as synonyms.

Steinmann (1979b) described *Labidura orientalis* from Nepal on a male. It was mainly differentiated by the absence of two spines on the hind margin of ultimate tergite. This character is variable in the samples of a large population. For this reason this species is considered as a synonym.
Uncertain species

*Labidura dharchulensis* Gangola
(Figs. 340-342)

Male: General colour brown to dark chestnut; head light brown; pronotum laterally yellow, prozona with two black spots posteriorly; elytra and wings blackish chestnut; legs yellowish, abdomen dorsally brown chestnut, darker laterally, ventrally in anterior half creamy white; forceps yellow.

Head triangular, slightly longer than broad, moderately convex above. Eyes prominent but shorter than post-ocular length. Pronotum quadrate, slightly narrowed posteriorly, all margins straight, median sulcus distinct, prozona raised and metazona weakly depressed. Elytra well developed, granulated, costal margin with raised carina, meeting along the inner margin. Wings short, of same texture as the elytra. Legs normal. Abdomen spindle shaped. Ultimate tergite transverse, rectangular, gently narrowed posteriorly, hind margin trisinuate, laterally above the branches of forceps oblique. Pygidium vertical, not visible from above. Forceps remote at base, gently incurved, tapering apically, internal margin with one or two teeth in apical half and crenulated in basal half. Genitalia as seen in fig. 342.

Female: Agrees with male in most characters except that the ultimate tergite more strongly narrowed posteriorly and forceps simple and almost straight.

*Types*: Holotype Male and Allotype Female – repository not known.

*Distribution*: India: U.P., Pithoragarh Dist., Dharchula, 915m. Known from the type locality only.

*Remarks*: According to the original description (Gangola, 1968) the types should be available in the Zoological Museum of Th. D.S.B. Government College, Nainital. On personal enquiry there it is now confirmed they are not present there.

On the basis of original description and figures this species agrees with smaller forms of *L. riparia* (Pallas). The figure of male genitalia shows that the distal lobes are flexed forward which perhaps represents the exerted condition of this part. It is not clear whether the apical portion of preputial sacs is clubbed or that of virga.
According to the description it is the former but diagram shows the latter. In any case, if former is taken as correct it may not be of much taxonomic importance since during mounting muscles of preputial sacs often get arranged in various shapes.

However, the species is retained as valid for the present pending examination of types.

Genus **Forcipula** Bolivar

Size medium to large (12.0 – 26.0 mm). Body elongated with a fine pubescence. Head convex; eyes shorter or longer than the area behind eyes; antennae 20-40 segmented; third long and cylindrical, slightly shorter than 1st and longer than the remaining segments; distal segments long and thin. Elytra well developed, often with a faint linear convexity along the costal margin. Wings well developed, sometimes absent. Abdomen long, cylindrical, sides of certain segments in males with spines or crests, sometimes poorly developed or absent, hind margin of tergites milled. Forceps, in male, long and slender, remote, curved or straight in basal half to two thirds afterwards bent inwards and straight, contiguous, remote basal part armed with a sharp tooth in middle or simply crenulate; parameres with a small epimerite apically. Female forceps simple, straight, armed near apex, internally with a sharp preapical tooth.

**Type species**: *Labidura quadrispinosa* Dohrn, 1863 (Designated by Kirby, 1904).

**Distribution**: Oriental Region and tropical parts of Africa and South America.

**Key to the species (on males only)**

Following key does not include *F. leonardi* Steinmann, since it is based on a female and its taxonomic position is doubtful.

1(6). Elytra with a week ridge (represented by a convexity) along the costal margin and tuberculated

2(5). General colouration yellowish brown; eyes about as long or longer than post ocular area; sides of abdominal segments with an oblique, triangular crest
3(4). Forceps with a single tooth inernally at the point of bend ...........................
..............................................................................................................F. lurida Boliver

4(3). Forceps with a pair of teeth internally at the point of bend..............................
..................................................................................................................F. tuberculata Srivastava

5(2). General colouration blackish brown; eyes shorter than post ocular area in length; sides of abdominal segments with a sharp spine..........................
..................................................................................................................F. quadrispinosa (Dohrn)

6(1). Elytra without a ridge along the costal margin, smooth or punctulate

7(10). Body covered with dense, long and short pubescence

8(9). Forceps with a sharp internal spine in the middle of basal remote portion in normal forms (in minor specimens tooth may be weakly developed or marked only by a faint protuberance); parameres apically acute ...............................F. trispinosa (Dohrn)

9(8). Forceps with minute distantly placed teeth in basal remote part; parameres more or less of uniform width with apex rounded......F. despinosa (Hebard)

10(7). Body covered with fine, comparatively sparse pubescence

11(16). Sides of certain abdominal segments with a single spine on each side

12(13). Forceps internally with a distinct spine, directed posteriorly, followed by a faint tubercle, at the middle of basal remote part ....................F. borellii Chopard

13(12). Forceps crenulate internally in basal remote part, without any sharp spine

14(15). Sides of abdominal segments 3rd to 5th with a sharp spine; forceps in basal remote part crenulate, terminating into a sharp point; parameres apically blunt ................................................................. aborensis Brindle

15(14). Sides of abdominal segments 3rd to 6th with a sharp spine; forceps in basal remote part only crenulate; parameres with apex acute ....F. indica Brindle

16(11). Sides of certain abdominal segments with a pair of spines, of unequal size; often poorly developed

17(18). Parameres comparatively narrower, of uniform width throughout, apex slightly obliquely truncate, apical epimerite curved ..............F. elongata Srivastava

18(17). Parameres comparatively broader, in apical one fourth a little narrower or broader, apical epimerite straight

19(20). Head behind eyes parallel sided; pronotum longer than broad, elytra and wings well developed; parameres, a little narrowed in apical one fourth with tip obtusely pointed ................................................................. F. clavata Liu

20(19). Head behind eyes gently expanded; pronotum generally about as long as broad, rarely a trifle longer; parameres gently expanded in apical one fourth with tip broadly rounded ........................................................................F. abbreviata Srivastava
Forcipula lurida Bolivar
(Figs. 343-345)

Forcipula quadrispinosa var lurida Bolivar, 1897, Annls. Soc. ent. Fr., 66: 283 (Male; Madras Presidency (India); Bormans and Krauss, 1900, Das Tierreich, Lief 11 : 31.

Male : General colour yellowish brown, legs yellow, abdomen laterally and forceps along the internal margin reddish brown. Finely pubescent on head and abdominal tergites. Head triangular, longer than broad, sutures distinct, frons and occiput raised, hind margin slightly emarginate in middle. Antennae 30-segmented or more, 1st stout, shorter than the distance between the bases of antennae, remaining typical of the genus. Eyes prominent, about as long as the post-ocular area. Pronotum longer than broad, widened posteriorly, sides slightly emarginate in middle, hind margin rounded, median suture distinct; prozona raised and metazona despressed. Elytra and wing well developed, rugose, former tuberculated and with faintly raised costal margin. Legs normal, hind tarsi with first segment slightly longer than the combined length of second and third, clad with thick pubescence on under side. Abdomen convex, punctulate, sides of abdominal segments 3rd to 5th with an oblique triangular tooth. Penultimate sternite triangular, rounded posteriorly with slight emargination in middle. Ultimate tergite transverse, faintly depressed in middle posteriorly, hind margin straight in middle and laterally above the bases of forceps concave and oblique. Forceps elongated, incurved in a little beyond basal half; afterwards contiguous and straight, tapering apically with tip pointed and hooked, internal margin ventrally dentate in incurved part and provided with a strong, posteriorly directed spine at the junction of basal incurved and apical straight part. Genitalia as seen in fig. 344; parameres long, slightly narrowed apically; apical epimerite short; virga distinct, basal vesicle large.

Female : Agrees with male in most characters except that penultimate sternite posteriorly obtuse in middle; sides of abdominal segments without spine; ultimate tergite weakly transverse and forceps simple and straight, internally crenulated but preapical tooth absent.
Figs. 343-345: Forcipula lurida Bolivar, Male; 343. Dorsal view; 344. A portion of genitalia showing paramere and distal lobe; Female; 345. Ultimate tergite and forceps.

Type: Type Male according to steinmann (1989a) in MNHP.

Distribution: India (Tamil Nadu, Uttar Pradesh, Bihar and Assam) and Sri Lanka.

Following specimens hitherto not reported are preserved in Z.S.I. : India : Assam, Goalpara, 4 Males, 4 Females, April, 1966 (R.C.Basu coll.).

Remarks: The present observations are based on Males and Females from North India (Rishikesh) and Assam (Goalpara) whereas the species was originally described from South India. In one male specimen forceps are almost straight showing the minor form of development and inner margin with small serrations only. It appears to be almost identical with F. tuberculata Srivastava, but the latter differs in having
pair of spines internally at the junction of basal remote and apical subcontiguous part of forceps. Should there be any intraspecific variation in this character, the latter will be placed as a synonym. For the present \textit{F. tuberculata} is treated as valid since the inner armature in normal males is generally observed as constant.

\textit{Forcipula tuberculata} Srivastava

(Figs. 346-349)

Male : General colour shining yellowish brown, head, antennae and pronotum darker; legs light yellow. Head slightly longer than broad, finely pubescent, sutures distinct, frons and occiput weakly convex, gently depressed in middle at the junction of median and transverse sutures. Eyes large, prominent, about twice as long as the post-ocular area. Antennae 35-segmented; 2\textsuperscript{nd} small, equal to 4\textsuperscript{th}; 3\textsuperscript{rd} long, cylindrical, equal to 4\textsuperscript{th} and 5\textsuperscript{th} together, remaining long and thin, gradually increasing in length. Pronotum longer than broad, lateral margins gently emarginate in middle, hind margin broadly rounded, median sulcus distinct; prozona tumid, well differentiated from flat metazona. Elytra twice as long as pronotum, translucent, tuberculated, hind margin truncate. Wings slightly longer than the pronotum, opaque, of same texture as elytra. Abdomen finely punctulated, gently expanded posteriorly, sides of segments 3\textsuperscript{rd} to 5\textsuperscript{th} with an oblique, triangular, serrated ridge. Penultimate sternite ample, triangular, posteriorly obtuse in middle with a slight emargination in middle. Forceps remote, with an oblique ridge above at base, incurved up to a little beyond middle, thence almost straight, subcontiguous, tapering with apices hooked and pointed, internally dentate below in basal one third, provided with a sharp tooth at the point of bend followed by another similar one but slightly smaller. Genitalia as seen in fig. 348-349.

Female : Agrees with males in most character except penultimate sternite and ultimate tergite more narrowed posteriorly and forceps simple and straight, internally crenulate with a distinct preapical tooth.

\textit{Measurements} : (in mm)

\textit{Types} : Holotype Male in ZSI.

\textit{Distribution} : India (Arunachal Pradesh, Assam, West Bengal and Orissa).
Following specimen present in ZSI collection was not reported earlier: India: Orissa, Cuttack, 1 Male (genitalia mounted between two coverslips and attached to the pin of specimen), 23.12.1970, at light (S. Khera coll).

Remarks: This species has a close resemblance with *Forcipula lurida* Bolivar, known from Madras, in general body colour and the shape of lateral abdominal spines but it can be easily separated by the presence of large eyes, about twice as long as the post ocular area; translucent and tuberculated elytra and forceps with a pair of sharp spines internally, of which the posterior one is smaller and situated a little beyond middle. The parameres of the type have deep constrictions on external margin which may be due to shrinkage during mounting since the above specimen from Orissa has the external margin entire. The tuberculate elytra in this species recalls *F. banksi* Borelli, described from Philippines.

It may be mentioned here that Brindle (1966) has placed *F. lurida* Bolivar in *quadrispinosa* group because of the rugose elytra.
**Forcipula quadrispinosa** (Dohrn)
(Figs. 350-354)

Male: General colour dark blackish brown, antennae, legs and sides of pronotum blackish brown; finely pubescent.

Head slightly longer than broad, sutures faint. Eyes about half as long as the postocular area. Antennae 35-segmented; 1st segment, stout expanded apically, slightly shorter than the distance between antennal bases; 2nd about as long as broad; 3rd long, slender, about twice as long as broad; 4th & 5th subequal but shorter than 3rd, after that segments thinning and gradually increasing in length. Pronotum quadrate, a little longer than broad, anterior margin straight, sides gently convex, hind margin rounded, median sulcus faint; prozona tumid and metazona flat. Elytra well developed, rugose, costal margin with a linear convexity, humeral angles prominent; wings about as long as the pronotum, of the same texture as the elytra. Abdomen finely
SRIVASTAVA : Dermaptera

Tuberculated, gently dilated posteriorly, tergites milled along the hind margin, sides of segments 3rd to 5th with a sharp gently incurved spine, of which anterior and posterior pair reduced. Penultimate sternite rounded posteriorly. Ultimate tergite smooth, transverse, depressed in middle posteriorly, above base of forceps with a weak tumid elevation, median sulcus distinct, hind margin in middle straight, above base of forceps emarginate and oblique. Forceps in basal half strongly arcuate, in minor forms weakly so. Genitalia (figs. 353) with parameres about five times longer than broad, almost of uniform width, apex rounded and epimerite short.

Female: Agrees with male but sides of segments without spines; ultimate tergite narrowed posteriorly; forceps simple and straight, internally serrated near base, preapical tooth distinct.

Types: Type Male of Labidura quadrispinosa Dohrn, 1863 in UZMC according to Steinmann (1989a).

Type of Male of Forcipula jacobsoni Burr, 1908 in UZMC according to Steinmann (1989a).

Type female of Labidura morosa Kirby, 1891 in BMNH.

Holotype Male (nymph) of Genitalata mahajani Kapoor, 1974- repository not known; Paratype 1 nymph (not Male) in ZSI.

Distribution: India (extensively distributed all over India except beyond 3000 ft in Himalayas), Bhutan, Nepal, Myanmar, South China, Thailand, Indo-China, and Philippine Isls.

Also reported from Reunion and Mauritius.

Remarks: Specimens without tubercles on the sides of abdominal segments and weaker form of forceps are occasionally found in a large population.

Forcipula simplex Bey-Bienko (1970) was considered as a synonym by Srivastava (1986) since it represents the form with minor development of forceps and agrees with this species in almost all other characters.

Genitalata majahajani Kapoor 1974 is described on nymphs only. One Paratype labelled as “Rajgarh Road, Gaura, coll. H.P. Agrawal, 5.viii.1971” was examined by Srivastava (1986) which possesses somewhat rugose metanotal pads with a lateral rugose stripe. In all probabilities it represents nymphal stage of this species and was rightly treated as a synonym.
Forcipula trispinosa (Dohrn)
(Figs. 355-358)

Labidura (?) pugnax Kirby, 1891, *J. Linn. Soc. (Zool.)*, 25: 510, pl. 12, fig. 1 (Male, Female; North India).

Male: General colour blackish brown, shining; antennae, sides of pronotum, inner wing tips yellowish. Fine pubescence all over body including elytra and wings.

Head weakly convex, sutures faint, hind margin straight. Eyes shorter than postocular area. Antennae 30-segmented or more. Pronotum as broad as long, sides straight reflexed hind margin rounded, median sulcus distinct. Elytra finely punctulated, pubescent, ample, humeral angles prominent, smooth; wings lacking pubescence, otherwise same as elytra, about as long as pronotum. Legs typical of the genus, hind tarsi with basal segment slightly longer than apical two together. Abdomen finely punctulated, gradually expanding from base to apex, sides of segments 3rd to 5th with a sharp triangular spine, of which spine on the segment 5th shorter than
other segments, hind margin of tergites weakly milled. Penultimate sternite with hind margin obtuse in middle posteriorly. Ultimate tergite transverse, smooth, median sulcus represented by a distinct impression, feebly depressed in middle posteriorly, hind margin in middle straight or scarcely concave, laterally above base of forceps oblique. Forceps in basal 2/3 remote, straight, afterwards gently bend inwards and straight, tip gently hooked, internal margin in basal remote part crenulated with a sharp posteriorly directed tooth in middle. Genitalia with parameres long, narrowed apically with tip acute, apical epimerite short; distal lobes with virga distinct and basal vesicle large (fig. 357).

Female: Agrees with male but body more densely pubescent; ultimate tergite narrowed posteriorly; forceps with branches simple and straight, apices pointed, gently hooked, inner margin crenulate with a weak internal tooth at apical one third.

**Types**: Type Male of *Labidura trispinosa* Dohrn – unknown. Paratype 1 Male according to Steinmann (1980a) at HNAB.

Type Male, Female of *Labidura? pugnax* Kirby (1981) in BMNH; he has not mentioned the number of specimens in the original description of the species.

Holotype Male and Paratype 1 Male of *Forcipula afghana* Steinmann in HNAB.

**Distribution**: All along the Himalayas in India, Pakistan, Bhutan and Nepal.

In India it is known from Meghalaya (Khasi and Garo Hills) also. Also reported from Afghanistan.

**Remarks**: Occasionally in a large population a few male specimens lack or possess poorly developed spines on the sides of abdominal segments and forceps are almost straight or gently undulated with inner tooth poorly marked or wanting. Such specimens have been referred by Burr (1910) as var. *minor* of this species.

*Forcipula despinosa* Hebard

(Figs. 359-361)

Male: General colour dark brown, forceps slightly reddish, antennae and legs yellowish; strongly pubescent.

Head slightly longer than broad, frons and occiput weakly raised, sutures faint, hind margin straight. Eyes about half as long as the post ocular area. Antennae

(partly broken; 18 segments remaining on the left side) with 1st segment stout, clavate; 2nd small, about as long as broad; 3rd long and slender, only slightly shorter than 1st; 4th and 5th subequal and subclavate, remaining gradually increasing in length and becoming more slender distally. Pronotum slightly longer than broad, anterior margin convex, sides depressed and straight, hind margin briefly rounded; prozona weakly tumid, not well differentiated from weakly depressed metazona. Legs long and slender. Elytra and wings normal, former without any ridge on costal margin. Abdomen long and slender, feebly expanded posteriorly, surface with microreticulations, strongly pubescent above, pubescence longer on sides, hind margin of each tergite with a row of small compressed tubercles (like milling on the edge of a coin) which extend on sides as well, laterally without any large teeth but on segments 4th and 5th a small tubercle present, rather larger than usual row of compressed tubercles, reminiscent of a tooth. Penultimate sternite transverse, narrowed posteriorly with hind margin rounded. Ultimate tergite strongly transverse, surface with microreticulations, median longitudinal furrow deep and distinct. Pygidium vertical, narrowed apically with two minute points. Forceps long and slender, trigonal for a short distance at base above, internal margin concave in a little more than half of the length, afterwards straight, internally armed in basal half with sharp teeth, widely spaced, apices gently hooked which meet. Genitalia as seen in figs. 360-361.

Female: Unknown.

Types: Holotype Male at ANSP.

Distribution: Known from the type locality only.

Remarks: This species resembles strongly with *F. trispinosa* var. *minor* Burr, due to the presence of dense long and short pubescence on the body and lacking tooth on the sides of abdominal segments but differs by the shape of parameres which are rounded at apex.

In the latter apical portion of parameres are somewhat narrowed.

*Forcipula borellii* Chopard  
(Figs. 362-365)

Male: General colour dark blackish brown; sides of pronotum pale; antennae and legs light brown or yellowish brown, finely pubescent, longer pubescence present on the sides of abdominal segments.

Head somewhat depressed, longer than broad, sutures weakly marked, hind margin lightly emarginate in middle. Eyes prominent, only slightly shorter than post ocular area. Antennae 31-segmented, basal segment stout, expanded apically, shorter than the distance between antennal bases; 2 short, transverse; 3rd long, slender, three times as long as broad, longer than remaining segments; 4th and 5th stout, subequal, remaining gradually increasing in length distally and thining. Pronotum longer than broad, lateral margin straight, reflexed, almost of uniform width, hind angles and margin rounded; prozona tumid, metazona depressed. Elytra well developed, finely punctulate, truncate posteriorly; a small scutellum visible; wings abbreviated, concealed. Abdomen gradually expanded posteriorly, sides of segments 3rd to 5th with a sharp and hooked spine, on 6th segment a small tubercle present (absent in Cototype).
Penultimate sternite narrowed posteriorly, hind margin subtruncate in middle, punctulate. Ultimate tergite transverse, smooth, disc weakly convex, along the median sulcus and in middle posteriorly depressed, above the base of forceps with a small conical tubercle, hind margin in middle straight, laterally above base of forceps oblique. Pygidium vertical, narrowed posteriorly with hind margin briefly rounded. Forceps with branches in basal two third remote, elongately curved, near base above trigonal, afterwards depressed, internally armed at middle with a sharp, posteriorly directed triangular tooth, followed by a tubercle, and finely serrated, afterwards, after a weak bend at apical third branches subcontiguous, apices hooked. Genitalia with parameres six times longer than broad, narrowed apically with tip obtuse, epimerite, short, virga distinct with a basal vesicle (Fig. 364).

Female: Agrees with male in most characters except that sides of abdominal segments without spines; ultimate tergite narrowed posteriorly; forceps simple, contiguous and straight, inner margin crenulate in basal half, afterwards unarmed except for a blunt tooth near apical one third.

Types: Types Male, Female; Cotypes 1 Male, 2 Females and 9 nymphs from India: Meghalaya, 2.1922 (S.W. Kemp and B.N. Chopra coll.) in Z.S.I.

Distribution: India: Assam, Meghalaya and Sikkim

Forcipula aborensis Brindle

(Figs. 366-367)

Forcipula pugnax (né Kirby) Burr, 1913 Rec. Indian Mus., 8(2) : 139.

Male: General color dark brownish black, antennae, sides of pronotum and legs yellowish brown, finely pubescent.

Head slightly longer than broad, weakly convex, sutures distinct, hind margin straight. Eyes prominent, about half as long as post-ocular area. Antennae 35-segmented, first segment stout, shorter than the distance between antennal bases; 2nd short, transverse; 3rd long, slender, a little over twice as long as broad, longer than most of the segments except a few apical ones; 4th and 5th globular and subequal, afterwards segments gradually increasing in length and thinning, a few apical ones thin and rod shaped. Pronotum longer than broad, sides straight, gently reflexed, hind margin rounded, median sulcus distinct in apical half; prozona tumid and well differentiated from flat metazona. Elytra obscurely punctuated, pubescent, meeting along the suture, hind margin truncate; wings concealed. Legs typical of the genus, and hind tarsi with 1st segment, slightly longer than the combined length of 2nd and 3rd; 2nd longer than broad. Abdomen obscurely punctuated, gradually dilated posteriorly, sides of segments 3rd to 5th with a single hooked spine, spine on 5th segment very much reduced. Ultimate tergite smooth, transverse, depressed along the median suture and in middle posteriorly, above base of forceps with a faintly tumid elevation, hind margin in middle, straight, above base of forceps oblique. Pygidium vertical, narrowed posteriorly with hind margin rounded. Forceps with branches remote in basal two thirds or more bent inwards, afterwards subcontiguous with tip hooked, internal margin with small rounded tubercles, in normal males, in the basal remote part with a sharp spine in apical half. Parameres long, tip obtuse; virga distinct with basal vesicle (fig. 367).

Female: Agrees with male most characters but slightly shorter in size; ultimate tergite narrowed backwards; forceps with branches straight, apices gently incurved and crossing, internally finely crenulate with a distinct tooth near apex.

**Types**: Holotype Male in BMNH.

**Distribution**: India: Arunachal Pradesh, Siang and Tirap dists.

**Remarks**: This species is apparently closely related to *F. abbreviata* Srivastava and *F. clavata* Liu, but differs in having a single thorn like spine on the sides of abdominal segments 3rd to 5th besides the characteristic parameres.

*Forcipula indica* Brindle
(Figs. 368-370)

Figs. 368-370: *Forcipula indica* Brindle, Male; 368. Dorsal view; 369. Paramere, enlarged; Female; 370. Ultimate tergite and forceps.

Male: General colour shining blackish brown, antennae, legs, sides of pronotum and inner margin of wings yellow. Finely and densely pubescent except wings, ultimate tergite and forceps.

Head slightly longer than broad, sutures faint or distinct, hind margin faintly emarginate in middle. Eyes much shorter than post-ocular area. Antennae 35-40-
segmented; basal segment stout, expanded apically, shorter than the distance between antennal bases; 2nd short, transverse; 3rd long, slender, a little over twice as long as broad; 4th and 5th subequal but shorter than 3rd; 6th onwards gradually increasing in length and thinning. Pronotum longer than broad, sides straight and gently reflexed, hind margin briefly rounded, median sulcus distinct; prozona tumid, metazona depressed. Elytra three times longer than the pronotum, obscurely punctulate, humeral angles prominent, hind margin very slightly truncate, oblique; wings about as long as the pronotum, smooth. Legs typical of the genus, hind tarsi with first segment slightly longer than the combined length of second and third segments. Abdomen punctulate, gradually expanded posteriorly, tergites milled along the posterior margin, sides of segments 3rd to 6th with a sharp spine, of which on the segment 6th often very much reduced in the form of a tubercle. Penultimate sternite triangular with posterior margin scarcely emarginate in middle. Ultimate tergite, smooth, transverse, disc convex, depressed in middle posteriorly, median sulcus distinct, above the base of forceps feebly tumid, hind margin in middle straight, laterally above base of forceps oblique. Forceps in basal two third remote, almost straight, near base above with a short ridge, otherwise depressed, internal margin in basal one third with fine tubercles and a blunt tooth at the point of bend, in apical one third branches subcontiguous, straight, apices hooked. Genitalia with parameres acute apically (fig. 369).

Female: Agrees with male in most characters but pubescence more thick; sides of abdominal segments lack spines; ultimate tergite gently narrowed posteriorly; forceps simple, straight, tapering to pointed and gently incurved apices which meet, inner margin with a weak tooth at apical one third.

**Types:** Holotype Male, Paratype Male in BMNH.

**Distribution:** India (Arunachal Pradesh, Assam, Meghalaya and Sikkim) and Bhutan.

**Remarks:** Often in some males the forceps are straight and provided internally at about middle with a weak tubercle.

Occasionally individuals with minor development are met with which are smaller in size and are normally devoid of spines on the sides of abdominal segments. Forceps are almost straight, sometimes only a little undulate at about middle.

*Forcipula elongata* Srivastava
(Figs. 371-373)

Male: General colour dark brownish black with slight variation to dark brown on certain body parts. Antennae blackish brown with 3rd segment in basal two thirds and legs yellowish brown, knee joints and femora very feebly shaded with a fuscous patch. Pubescence short and fine, covered all over the body, on ultimate tergite and forceps sparse.

Head slightly longer than broad, weakly convex, at the junction of sutures with a feeble depression, region behind eyes parallel sided, sutures fine, hind margin hardly sinuate in middle. Eyes shorter than the post-ocular length. Antennae multi-segmented (apical portion broken); 1st stout, narrowed basally, shorter than the distance between antennal bases; 2nd transverse; 3rd slender, slightly longer than combined length of 4th and 5th; 5th slightly longer than preceding, remaining gradually increasing in length, apical ones very thin, almost rod shaped. Pronotum punctulate, slightly longer than broad, a trifle broader posteriorly, sides feebly emarginate in middle, anterior and posterior margins straight, postero-lateral angles well rounded,
prozona tumid with a small depression on either side of median line, metazona depressed, well differentiated from prozona by a faint depression, median suture represented by a smooth line. Elytra well developed, punctulate, humeral angle weak, meeting along the inner margin, hind margin feebly oblique. Wings wanting. Legs normal. Abdomen convex, gently dilated posteriorly, tergites with fine microreticulations and a pair of elongated smooth patches sublaterally, milled along the hind margin, milling (like that of coin on its edge) weaker or almost obsolete on last one or two tergites, sides of segments 4th to 6th with a pair of tubercles, of which ventral one very small and dorsal one larger and lobular. Penultimate sternite obtuse posteriorly, in middle with a slight emargination, along the median line in apical half a raised stripe present. Ultimate tergite smooth, strongly transverse, faintly depressed in middle posteriorly, median suture distinct, hind margin between branches of forceps straight and laterally concave and oblique. Forceps elongated, strongly bowed inwards in basal half, afterwards more or less straight or gently undulate but subremote, strongly tapering posteriorly with apices gently hooked, at base above with an oblique ridge, internally in basal half with a few crenulations, otherwise smooth. Parameres (fig. 372) long and narrow, tip obliquely truncate and apical epimerite curved.

Female: Agrees with male in most characters except that size smaller, penultimate sternite strongly triangular, ultimate tergite strongly narrowed posteriorly, forceps simple and straight, internal margin crenate and with a preapical tooth.

Measurements: (in mm)

Types: Holotype Male, Paratype 1 Male in ZSI.

Distribution: India: Tamil Nadu (Coimbatore Dist., Anamalai Hills, Cinchonã, 3500 ft.; Madura Dist, Shembaganur) and Kerala (Kottayam Dist., Kuttikkanum).

Remarks: This species has a close resemblance with F. abbreviata Srivastava, in having a pair of spines on the sides of certain abdominal segments but differs by the shape of spines in being lobular especially the dorsal one and ventral one very much reduced; parameres comparatively narrower with apical epimerite curved.

Forcipula clavata Liu
(Figs. 374-377)

Male: General colour dark brown to blackish brown; sides of pronotum, legs and wings along the internal margin in apical half testaceous yellow. Elytra and forceps somewhat reddish. Body finely pubescent.

Male: Head longer than broad, sutures distinct, smooth, frons and occiput moderately convex, post-ocular margin parallel, hind margin straight, with a faint
emargination in middle. Eyes shorter than the post-ocular length of head. Antennae typical of the genus. Elytra and wings well developed, former feebly punctate. Legs normal. Abdomen gradually dilated posteriorly, each tergite milled along the hind margin, sides of segments 3rd to 5th with a pair of spines of which dorsal one larger and hooked. Penultimate sternite transverse, hind margin rounded with a faint emargination in middle. Ultimate tergite transverse, median sulcus distinct. Pygidium vertical, triangular. Forceps curved or broadly so in basal half and contiguous, tapering and straight in apical half; internally crenulate below in basal half of curved part, ending into a sharp teeth. Genitalia Paramere as seen in fig. 376.

Female: Agrees with male in most characters except that the penultimate sternite and ultimate tergite more narrowed posteriorly; forceps simple and straight, trigonal in basal one third, internally crenulate with a triangular teeth at apical one third.

**Types** : Type Male, Female of *Forcipula clavata* Liu in MZSC.

Holotype Male of *Forcipula obscura* Steinmann in HANB.

**Distribution** : India: Arunachal Pradesh and Meghalaya.

Also reported from China (Chunking) and Vietnam.

**Remarks** : In some specimens, spines on the sides of abdominal segments 4th and 5th are very much reduced or totally absent on 3rd and the branches of forceps are almost straight, only slightly undulated in middle. Liu (1946) records wings as yellow but in the present series before me wings are brownish with inner margin in apical half and tip yellowish.

This species was considered as synonym of *F. decolyi* Bormans by Bey-Bienko (1959) but it is now resolved that latter is endemic to New Guinea and the material referred under this name from India and adjacent countries consists of two distinct species, viz. *Forcipula abbreviata* Srivastava from India and adjacent countries and *F. clavata* Liu, described from China.

It can be easily separated from *F. decolyi* Bormans and *F. abbreviata* Srivastava by the shape of pronotum being longer than broad; presence of well developed wings and distinctive parameres which are narrowed apically with tip obtusely pointed.

**Forcipula abbreviata** Srivastava

(Figs. 378-381)

General colour dark brownish black, sides of pronotum lighter in colour, often elytra in middle close to sutural margin and branches of forceps reddish; mouthparts, antennae and legs yellow or yellowish brown. Body finely pubescent.

Male: Head slightly longer than broad, sutures faintly marked, frons and occiput feebly raised, head gently widened behind eyes, hind margin convex with a faint emargination in middle. Antennae 30-segmented or more, basal segment widened apically and shorter than the distance between antennal bases; 2nd small, transverse; 3rd long and slender, only slightly shorter than 1st; 4th about as long as broad; 5th and 6th stout, cylindrical; 7th onwards segments narrowed at base and expanded apically and gradually increasing in length, certain preapical segments long and thin. Eyes prominent, slightly shorter than the post-ocular length. Pronotum about as long as broad or a trifle longer, smooth, sides straight, feebly concave in middle, hind margin and angles rounded, median sulcus distinct; prozona raised and metazona depressed. Legs typical of the genus. Elytra normal, feebly punctate, meeting along the sutural margin; small scutellum visible. Wings abbreviated, concealed. Abdomen convex, enlarging posteriorly, hind margin of each tergite milled but milling weaker on anterior and posterior tergites, sides of segment 3rd to 5th provided with a pair of spines, of which dorsal one larger, triangular and directed laterally, ventral one smaller and stumpy. Penultimate sternite transverse, hind margin narrowed posteriorly and rounded; manubrium short, about 1/5 as long as the sternite, about three times longer than broad. Pygidium vertical, triangular. Ultimate tergite transverse, smooth, hind margin straight in middle, oblique and concave laterally, median sulcus distinct. Forceps remote at base, with an oblique ridge at base above, afterwards branches depressed, curved in basal half enclosing an oblonge space, internal margin below tuberculated; afterwards straight, contiguous, tapering with apices gently hooked and pointed. Genitalia as seen in fig. 380.

Female: Agrees with male in most characters except that the penultimate sternite and ultimate tergite more narrowed posteriorly and forceps simple and straight, contiguous, internally crenulated with a large tooth at apical 1/3.

Types: Holotype Male and Paratypes 7 Males and 17 Females in ZSI.

Distribution: India: Arunachal Pradesh, West Bengal (Darjeeling Dist.) and Sikkim.

It occurs all along the Himalaya in India, Nepal and Bhutan.

Remarks: This species was confused with Forcipula decolyi Bormans, known from New Guinea, but differs by the shape of forceps which lack on internal margin below a large sharp pointed, posteriorly directed tooth and the parameres somewhat more
distinctly enlarged apically with tip rounded. In the latter (paratype 1 Male examined) shows that parameres are comparatively narrower apically with inner apical margin oblique and tip obtusely pointed.

All records of *F. decolyi* Bormans, from India, Myanmar, Nepal and Bhutan are referrable to the this species barring those that are based on fully winged forms which belong to another species, *F. clavata* Liu, from China.

The body size varies greatly and in the smaller males lateral abdominal spines are poorly developed, occasionally represented by a small single spine on 4th and 5th tergites and the curvature of forceps in basal half is more elongated.

It occurs commonly along the banks of rivers and streams under stones, right from the foot hills to higher elevations in Himalaya.

**Uncertain species**

*Forcipula leonardi* Steinmann

Female : General colour reddish brown, head red, antennae dark brown, pronotum black, yellow laterally, tegmina and abdomen reddish brown, former along the inner margin with light reddish stripe, wings yellow with tip light brown, legs dark brown.

Head broader than pronotum, sutures distinct. Antennae 27-segmented, 1st longer than the distance between antennal bases; 2nd short; 3rd twice as long as 4th. Pronotum almost square, sides parallel, hind margin rounded. Elytra and wings well developed, rugose. Legs normal. Abdomen elongated, punctate. Ultimate tergite transverse, narrowed posteriorly. Forceps almost straight, tapering with apices gently hooked, at base above trigonal, inner margin dentate in basal ¾ only.

Pygidicrania siamensis (née Dohrn); Burr, 1910, Fauna British India, Dermaptera: 59 (Partim).

Male : General colour chocolate brown; forceps lighter; head with a broad yellow patch on frons and occiput partially; pronotum yellow with dark leniar stripe close to median line, elytra with an oblong yellow stripe from shoulder to apical 1/3 and another narrower one laterally; antennae and wing yellowish; legs yellowish brown.

Head longer than broad, smooth, sutures fine, frons depressed, hind margin emarginate in middle. Eyes prominent, about as long as the post-ocular area. Antennae (partly broken) 20-segmented or more, basal segment stout, a trifle shorter than the distance between antennal bases; 2nd short, transverse; 3rd slightly longer than broad; 4th to 6th transverse, afterwards gradually thinning and increasing in length; occasionally antennae of other side from 4th to 6th not transverse, more elongated. Pronotum slightly longer than broad, sides rounded, hind margin subtruncate, median sulcus obsolete; prozona tumid, well differentiated from flat metazona. Tegmina and wings well developed. Legs typical of the genus. Abdomen cylindrical, gradually expanding posteriorly, tergites convex, obscurely punctulated, finely pubescent. Penultimate sternite finely pubescent, narrowed posteriorly with hind margin in middle subtruncate, in posterior half with three depressed stripes in middle. Ultimate tergite weakly transverse, finely pubescent, rugosely striate, expanded posteriorly, median sulcus faint, disc convex sloping on sides, hind margin incassate, in middle sub truncate, above base of forceps faintly oblique and sinuate, postero-lateral angles projecting, in the middle above close to hind margin with raised triangular, smooth area. Forceps with branches short, stout, flat, feebly bent in middle, narrowed posteriorly with tip hooked, at base externally with a constriction, internally enclosing a pear shaped area in basal 2/3 and in apical 1/3 elongated area, internal margin at base with two or three blunt tooth, afterwards with fine serrations, at apical 2/3 a sharp tooth present.

Female : Agrees with male except abdomen parallel on sides; penultimate sternite subtriangular with hind margin obtuse in middle; ultimate tergite quadrate, rugose
especially posteriorly with a triangular smooth area and forceps subcontiguous, trigonal, tapering, straight except at extreme apex, inner margin crenulated.

Distribution: Malay Peninsula, Sumatra, Java and India (Andaman Islands).

Types: Type Male in ZMHB.

Remarks: This species is very close to *Pygidicrana siamensis* (Dohrn, 1863) from Thailand but differs by the slight differences in the shape of parameres.

**ADDENDA TO PART – II**

*Mongolabis affinis* Ramamurthi

(Figs. 1-6)

General colour black; mouth parts reddish black; antennae slightly lighter; femora yellowish brown with dark band, tibiae and tarsi uniformly yellowish brown.

Head about as long as broad, smooth, sutures finely marked or obsolete, hind margin feebly emarginate in middle. Eyes shorter than post-ocular area. Antennae multisegmented, 1st stout, narrowed at base, about as long as the antennal bases; 2nd short; 3rd long, slender; 4th a little shorter than 3rd but stouter; 5th almost equal to preceding; 6th onwards segments gradually thinning; basal antennal segments diamorphic. Pronotum quadrate, gently transverse, lateral margin straight, gently reflexed and widened posteriorly with lateral angles rounded and margin subtruncate, prozona and metazona weakly raised, median sulcus short. Meso- and metanotum transverse, former with hind margin truncate and latter broadly emarginate. Legs typical of the genus. Abdomen gradually enlarging posteriorly, tergites convex, smooth, finely pubescent, sides of segments 7-9 acute angled, rugose. Penultimate sternite transverse, narrowed posteriorly with hind margin deeply sinuate. Ultimate tergite transverse, disc weakly raised with sparse punctuation, laterally rugose. Forceps trigonal and broad at base, narrowing towards apex, asymmetrical, right branch more strongly incurved than the left; inner margin crenulate. Genitalia as seen in figs. 5-6.

Female: Agrees with males in most characters except that ultimate tergite uniformly smooth, narrowed posteriorly; penultimate sternite triangular and forceps simple, straight.

**Distribution**: Thailand (Doi Suthep and Phu Kradung, NE Thailand) and India (Arunachal Pradesh).

The above record from India is based upon the following specimens present in the National Zoological Collection at the Zoological Survey of India, Calcutta:

India: Arunachal Pradesh; Upper Subansiri Dist., Around Don, 2 Males (genitalia mounted between two coverslips and attached to the specimens), 2 Females, *ca* 1500 ft., ex decaying log, 14.ii.1985, Coll. & determinted by G.K.Srivastava.

**Types**: Holotype Male, Allotype Female; Paratypes 2 Males, 6 Females, 6 Nymphs in UZMC.

**Remarks**: This species can be easily separated from the only known species of the genus from India, namely *Mongolabis vallakadaiensis* (Ramamurthi and David) in having pronotum slightly transverse (*vs* longer than broad in *M. vallakadaiensis*);
apterous (*us* Mesosternum with abbreviated elytra, narrowed at base, exposing a transverse scutellum and posteriorly lobed, overlapping along the middle line); sides of abdominal segments acute angled posteriorly and rugose (*us* convex posteriorly & ecarinate) and penultimate sternite with hind margin deeply emarginate (*us* convex).

**Apolabis thushargiriensis** sp.n.  
(Figs. 7-12)

General dark brownish black, mouth parts and legs yellowish brown; three basal antennal segments blackish brown.

Head longer than broad; frons and occiput raised, latter micro-reticulated, sutures fine, median one marked by a deep furrow, hind margin emarginate in middle. Eyes shorter than the post-ocular area. Antennae 19-segmented, basal segment stout, expanded apically, about as long as the distance between antennal bases; 2nd short, about as long as broad; 3rd long, slender twice as long as broad; 4th a trifle longer than broad, globular; 5th almost equal to preceding; 6th onwards gradually increasing in length, 11th onwards thinning, a few apical ones rod shaped. Pronotum longer than broad, smooth, lateral margin straight, parallel, gently reflexed, hind margin subrotundate, prozona and metazona weakly raised, median sulcus faint. Elytra narrowed at base exposing a transverse, triangular scutellum, smooth, broad apically, internal margin overlapping. Metanotum transverse, obscurely punctulate, hind margin broadly emarginate. Legs typical of the genus, hind tarsi with 1st segment slightly longer than the combined length of remaining two segments. Abdomen elongated, gently widened in middle, tergites convex, punctulate, laterally above with a pair of rounded, smooth patches in basal half, sides of abdominal segments 6-9 obtuse angled, strongly punctulate, with carina on 7th-8th only. Penultimate sternite triangular, hind margin in middle obtuse. Ultimate tergite obscurely punctulate, transverse, sloping backwards, depressed in middle close to hind margin, hind margin in middle subtruncate, laterally straight, very slightly converging posteriorly, median sulcus short. Pygidium vertical, triangular. Forceps with branches subremote at base, gradually curving and tapering apically with apices hooked, right branch more strongly incurved in apical 1/3, trigonal in basal 1/4, afterwards depressed, internal margin of left branch deplanate and convex near base and that of right sinuate with one or two teeth, otherwise unarmed. Genitalia as seen in figs 10-11.

Female: Agrees with males in most characters except that ultimate tergite strongly narrowed posteriorly and forceps simple and straight, internally armed with a small tooth at basal 1/3.

**Measurements**: (in mm)

**Material examined**: India: Kerala, Calicut dist., Thushargiri, ca 1500 ft., Holotype Male (genitalia mounted between two coverslips and pinned with the specimen), Paratypes: 2 Males, 2 Females and 1 nymph, 3.iii.2001 (G.K.Srivastava Coll.).

**Distribution**: India (Kerala).

**Types**: Holotype Male, Paratypes 2 Males, 2 Females and 1 nymph in Z.S.I.

**Remarks**: Some variations have been noted in the development of longitudinal carina on the sides of abdominal segments. It is present on 7-9 segments in one Paratype whereas it is absent in another male. Perhaps the other male may not be fully developed.

This species comes close to *Apolabis genitalis* (Kapoor) and *A. ramachandrai* (Ramamuarthi and David) in having the sides of certain abdominal segments carinate and penultimate sternites obtuse in middle posteriorly but differs from both in having the pronotum slightly broader than long. It however, can be, further differentiated from the latter by the shape of sides of abdominal segments 6-9 obtuse angled and the lateral margin of parameres convex.

Dr. Gyanendra Kumar Srivastava took his M.Sc. degree in Zoology from the Agra University, Agra in 1960. He was awarded from the same university Ph.D. and D.Sc. in the years 1973 and 1994 on his theses on Oriental Dermaptera. He has to his credit a little over 130 research papers published in National and International Journals dealing with taxonomy, zoogeography and biology of Dermaptera from India and other countries of the world, in particular and other insects, in general. His monographic publication include "Catalogue on Oriental Dermaptera" and Fauna of India, Dermaptera Pt. I superfamily Pygidicranoida besides publications relating to world revision of several supergeneric taxa. He is considered a world authority on the group.

Dr. Srivastava, has retired as Scientist F, in the year 2001 from the Zoological Survey of India, Kolkata.
